# **BQ25616/616J Standalone 1-Cell 3.0-A Buck Battery Charger with Power Path and 1.2-A Boost Operation**

**Technical [Documents](http://www.ti.com/product/BQ25616?dcmp=dsproject&hqs=td&#doctype2)** 

## <span id="page-0-1"></span>**1 Features**

- <span id="page-0-2"></span>High-efficiency, 1.5-MHz, synchronous switchmode buck charger
	- 92% charge efficiency at 2-A from 5-V input
	- $±0.5%$  charge voltage regulation
	- Adjustable charge voltage from VSET pin supports 4.1-V, 4.2-V, and 4.35-V with ±0.4% regulation accuracy
	- $±6%$  charge current regulation
	- $\pm$ 7.5% input current regulation
	- Supports JEITA (BQ25616J) or Hot/Cold (BQ25616) temperature sensing profile
	- 20-hr charging safety timer
- Support USB On-The-Go (OTG)
	- 5-V boost converter with up to 1.2-A output
	- 92% boost efficiency at 1-A output
	- Accurate constant current (CC) limit
	- Soft-start up to 500-µF capacitive load
	- PFM mode for light load operation
- Single input supporting USB input, high-voltage adapter, or wireless power
	- Support 4-V to 13.5-V input voltage range with 22-V absolute max input rating
	- 130-ns fast turn-off with optional external OVPFET standing input voltage up to 30 V
	- Programmable input current limit (IINDPM) with ILIM pin
	- VINDPM threshold automatically tracks battery voltage for maximum power
	- Auto detect USB SDP, CDP, DCP and nonstandard adaptors
- <span id="page-0-0"></span>• Narrow VDC (NVDC) power path management
	- System instant-on with no battery or deeply discharged battery
- Low  $R_{DSON}$  19.5-m $\Omega$  BATFET to minimize charging loss and extend battery run time
- 9.5-µA low battery leakage current with system standby
- High integration includes all MOSFETs, current sensing and loop compensation

## **3 Description**

The BQ25616/616J is a highly integrated 3-A switchmode battery charge management and system power path management device for single cell Li-Ion and Lipolymer batteries. The solution is highly integrated with input reverse-blocking FET (RBFET, Q1), highside switching FET (HSFET, Q2), low-side switching FET (LSFET, Q3), and battery FET (BATFET, Q4) between system and battery. The low impedance power path optimizes switch-mode operation efficiency, reduces battery charging time and extends battery run time during discharging phase.

The BQ25616/616J is a highly integrated 3-A switchmode battery charge management and system Power Path management device for Li-ion and Li-polymer batteries. It features fast charging with high input voltage support for a wide range of applications including speakers, industrial, and medical portable devices. Its low impedance power path optimizes switch-mode operation efficiency, reduces battery charging time, and extends battery run time during discharging phase. Its input voltage and current regulation deliver maximum charging power to the battery.

# <span id="page-1-0"></span>**4 Revision History**

## <span id="page-2-0"></span>**5 Description (continued)**

The solution is highly integrated with input reverse-blocking FET (RBFET, Q1), high-side switching FET (HSFET, Q2), low-side switching FET (LSFET, Q3), and battery FET (BATFET, Q4) between system and battery. It also integrates the bootstrap diode for the high-side gate drive for simplified system design. The hardware setting and status report provides easy configuration to set up the charging solution.

The device supports a wide range of input sources, including standard USB host port, USB charging port, USB compliant high voltage adapter and wireless power. It is compliant with USB 2.0 and USB 3.0 power spec with input current and voltage regulation. The device sets default input current limit based on the built-in USB detection through D+/D- pins. When the device built-in USB interface identifies the input adaptor is unknown, the device's input current limit is determined by the ILIM pin setting resistor value.

The device integrates the buck charger and boost regulator into one solution with single inductor. It meets USB On-The-Go (OTG) operation power rating specification by supplying 5-V with constant current limit up to 1.2-A.

The Power Path management regulates the system slightly above battery voltage but does not drop below 3.5-V minimum system voltage with adapter applied. With this feature, the system maintains operation even when the battery is completely depleted or removed. When the input current limit or voltage limit is reached, the Power Path management automatically reduces the charge current. As the system load continues to increase, the battery starts to discharge the battery until the system power requirement is met. This supplement mode prevents overloading the input source.

The device initiates and completes a charging cycle without software control. It senses the battery voltage and charges the battery in three phases: pre-conditioning, constant current and constant voltage. At the end of the charging cycle, the charger automatically terminates when the charge current is below a preset limit and the battery voltage is higher than the recharge threshold. If the fully charged battery falls below the recharge threshold, the charger automatically starts another charging cycle.

The charger provides various safety features for battery charging and system operations, including battery negative temperature coefficient thermistor monitoring, charging safety timer and overvoltage and over-current protections. Thermal regulation reduces charge current when the junction temperature exceeds 110°C. The STAT output reports the charging status and any fault conditions.

## <span id="page-14-1"></span>**9.1 Overview**

The BQ25616/616J device is a highly integrated 3.0-A switch-mode battery charger for single cell Li-Ion and Lipolymer battery. It includes the input reverse-blocking FET (RBFET, Q1), high-side switching FET (HSFET, Q2), low-side switching FET (LSFET, Q3), and battery FET (BATFET, Q4), and bootstrap diode for the high-side gate drive.

## <span id="page-14-2"></span>**9.2 Functional Block Diagram**

#### <span id="page-15-0"></span>**9.3 Feature Description**

#### **9.3.1 Power-On-Reset (POR)**

The device powers internal bias circuits from the higher voltage of VBUS and BAT. When  $V_{VBLIS}$  rises above  $V_{VBUS}$  <sub>UVLOZ</sub> or  $V_{BAT}$  rises above  $V_{BAT}$  <sub>UVLOZ</sub>, the sleep comparator, battery depletion comparator and BATFET driver are active.

#### **9.3.2 Device Power Up from Battery without Input Source**

If only the battery is present and the voltage is above depletion threshold ( $V_{BAT}$ <sub>DPLZ</sub>), the BATFET turns on and connects the battery to the system. The REGN stays off to minimize the quiescent current. The low  $R_{DSON}$  of BATFET and the low quiescent current on BAT minimize the conduction loss and maximize the battery run time.

The device always monitors the discharge current through BATFET. When the system is overloaded or shorted  $(I<sub>BAT</sub> > I<sub>SYS OCP</sub>_{Q4})$ , the device turns off BATFET immediately until the input source plugs in again.

#### **9.3.3 Power Up from Input Source**

When an input source is plugged in, the device checks the input source voltage to turn on the REGN LDO and all the bias circuits. It detects and sets the input current limit before the buck converter is started. The power up sequence from input source is as listed:

- 1. Power Up ACFET, see Power Up [ACFET](#page-15-1) section (optional)
- 2. Power Up REGN LDO, see Power Up [REGN](#page-16-0) LDO section
- 3. Poor Source Qualification, see Poor Source [Qualification](#page-16-1) section
- 4. Input Source Type Detection is based on D+/D– to set default input current limit (IINDPM threshold), see Input Source Type Detection (IINDPM [Threshold\)](#page-16-2) section
- 5. Input Voltage Limit Threshold Setting (VINDPM threshold), see Input Voltage Limit [Threshold](#page-17-0) Setting (VINDPM [Threshold\)](#page-17-0) section
- 6. Power Up Converter, see Power Up [Converter](#page-18-0) in Buck Mode section

#### <span id="page-15-1"></span>*9.3.3.1 Power Up ACFET*

The external ACFET provides an additional layer of voltage protection for the device. During input surge up to 30 V, the charger turns off ACFET and converter with 130-ns response time to disconnect VBUS from VAC. If users don't need ACFET, they shall connect VAC to VBUS and keep ACDRV pin floating. The ACFET is enabled when all the below conditions are valid.

The ACFET is enabled when all the below conditions are valid.

- $V_{\text{VAC PRESENT}} < V_{\text{VAC}} < V_{\text{ACOV}}$ .
- After  $t_{\text{DEB}}$  (15 ms typ) delay is completed

If one of the above conditions is not valid, ACFET keeps off. The battery powers the system If it is present.

## **Feature Description (continued)**

Note: beginning of blue lines indicate the trigger, and the arrow end of the blue line indicates the action

### **Figure 8. ACFET Startup Control**

## <span id="page-16-0"></span>*9.3.3.2 Power Up REGN LDO*

The REGN LDO supplies internal bias circuits as well as the HSFET and LSFET gate drive. It also provides the bias rail to TS external resistors. The pull-up rail of STAT can be connected to REGN as well. The REGN LDO is enabled when all the below conditions are valid:

- $V_{VBUS}$  >  $V_{VBUS_UVLOZ}$
- In buck mode, ACFET turns on,  $V_{VBUS} > V_{BAT} + V_{SLEEPZ}$
- In boost mode,  $V_{VBIJS} < V_{BAT} + V_{SI FFP}$ .
- After 220-ms delay is completed

During high impedance mode, REGN LDO turns off. The battery powers up the system.

#### <span id="page-16-1"></span>*9.3.3.3 Poor Source Qualification*

After the REGN LDO powers up, the device starts to check current capability of the input source. The first step is poor source detection.

VBUS voltage above  $V_{POORSRC}$  when pulling  $I_{BADSRC}$  (typical 30 mA)

If the device fails the poor source detection, it repeats poor source qualification every 2 seconds.

#### <span id="page-16-2"></span>*9.3.3.4 Input Source Type Detection (IINDPM Threshold)*

After poor source detection, the device runs input source detection through D+/D– lines. The D+/D– detection follows the USB Battery Charging Specification 1.2 (BC1.2) to detect standard (SDP/CDP/DCP) and nonstandard adapters through USB D+/D– lines.

#### **9.3.3.4.1 D+/D– Detection Sets Input Current Limit**

The device contains a D+/D– based input source detection to set the input current limit when a 5-V adapter is plugged-in. The D+/D– detection includes standard USB BC1.2 and non-standard adapters. When an input source is plugged in, the device starts standard USB BC1.2 detection. The USB BC1.2 is capable of identifying Standard Downstream Port (SDP), Charging Downstream Port (CDP) and Dedicated Charging Port (DCP). The non-standard detection is used to distinguish vendor specific adapters (Apple and Samsung) based on their unique dividers on the D+/D– pins. If an adapter is detected as DCP, the input current limit is set at 2.4-A. If an adapter is detected as unknown, the input current limit is set by ILIM pin.

The D+/D– automatically runs when adapter plugs in. The D+/D– detection contains three steps, DCD (Data Contact Detection), primary detection, and secondary detection.

Copyright © 2020, Texas Instruments Incorporated *Submit [Documentation](http://www.ti.com/feedbackform/techdocfeedback?litnum=SLUSDF7&partnum=BQ25616) Feedback*

### **Feature Description (continued)**

DCD (Data Contact Detection) uses a current source to detect when the D+/D– pins have made contact during an attach event. The protocol for data contact detect is as follows:

- Detect VBUS present and VBUS\_GD (pass poor source detection)
- Turn on D+  $I_{DP,SRC}$  and the D– pull-down resistor  $R_{DM,DW}$  for 13 ms
- If the USB connector is properly attached, the D+ line goes from HIGH to LOW, wait up to 0.5 sec. When the DCD timer of 0.5 sec is expired, the non-standard adapter detection is applied to set the input current limit.
- Turn off  $I_{DP,SRC}$  and disconnect  $R_{DM,DWN}$

The primary detection is used to distinguish between USB host (Standard Down Stream Port, or SDP) and different type of charging ports (Charging Down Stream Port, or CDP, and Dedicated Charging Port, or DCP). The protocol for primary detection is as follows:

- Turn on  $V_{DP-SRC}$  on D+ and  $I_{DM-Sink}$  on D– for 40 ms
- If portable device is attached to a USB host (SDP), the D– is below  $V_{REF-DAT}$ . Otherwise, it is attached to either CDP or DCP.
- Turn off  $V_{DP,SRC}$  and  $I_{DM,Sink}$

The secondary detection is used to distinguish two types of charging ports (CDP and DCP). The protocol for secondary detection is as follows:

- Turn on  $V_{DM,SRC}$  on D- and  $I_{DP,Sink}$  on D+ for 40 ms
- If portable device is attached to a Charging Downstream Port (CDP), the D+ is below  $V_{DATARFF}$ . Otherwise, it is attached to DCP.
- Turn off  $V_{DM,SRC}$  and  $I_{DP,Sink}$

Most of the time, a CDP requires the portable device (such as smart phone, tablet) to send back an enumeration within 2.5 seconds of CDP plug-in. Otherwise, the port will power cycle back to SDP even the D+/D– detection indicates CDP.

#### **Table 1. Non-Standard Adapter Detection**

#### <span id="page-17-0"></span>*9.3.3.5 Input Voltage Limit Threshold Setting (VINDPM Threshold)*

The device has two modes to set the VINDPM threshold.

- Fixed VINDPM threshold. The VINDPM is set at 4.3 V.
- VINDPM threshold tracks the battery voltage to optimize the converter headroom between input and output. The actual input voltage limit is the higher of the VINDPM setting (4.3-V) and  $V_{BAT}$  + 200 mV.

#### <span id="page-18-0"></span>*9.3.3.6 Power Up Converter in Buck Mode*

After the input current limit is set, the converter is enabled and the HSFET and LSFET start switching. The system voltage is powered from the converter instead of the battery. If battery charging is disabled, the BATFET turns off. Otherwise, the BATFET stays on to charge the battery.

The device provides soft-start when system rail is ramping up. When the system rail is below  $V_{BAT~SHORT}$ , the input current is limited to 200-mA. The system load shall be appropriately planned not to exceed the 200-mA IINDPM limit. After the system rises above  $V_{BAT}$  shortz, the device input current limit is the value set the by ILIM pin.

As a battery charger, the device deploys a highly efficient 1.5-MHz step-down switching regulator. The fixed frequency oscillator keeps tight control of the switching frequency under all conditions of input voltage, battery voltage, charge current and temperature simplifying output filter design.

The converter supports PFM operation by default for fast transient response during system voltage regulation and better light load efficiency.

#### **9.3.4 Boost Mode Operation From Battery**

The device supports boost converter operation to deliver power from the battery to other portable devices through a USB port. The output voltage is regulated at 5-V and output current is up to 1.2 A with constant current regulation.

The boost operation is enabled if the conditions below are valid:

- 1. OTG pin HIGH
- 2. VBUS less than  $V_{BAT} + V_{SLEEP}$  (in sleep mode) before converter starts.
- 3. Voltage at TS (thermistor) pin, as a percentage of  $V_{REGN}$ , is within acceptable range ( $V_{BHOT-RISE%}$  <  $V_{TS%}$  < V<sub>BCOLD</sub> FALL%)
- 4. After 30-ms delay from boost mode enable.
- 5. Not in any fault such as  $I_{\text{SYS OCP Q4}}$ , TSHUT, ACOV or VBUS OV.

The converter supports PFM operation at light load in boost mode.

#### **9.3.5 Standalone Charger**

The BQ25616/616J is a standalone device without host control. Any change on CE, ICHG and ILIM pins will cause a real time internal reference change. Charging is enabled or disabled via the CE pin. D+/D– and ILIM pins control the input current limit settings. D+/D– detection and VSET pin setting only takes effect upon adapter plug-in.

Charge current must be programmed to a value within a range of 300 mA to 3000 mA with a pull-down resistor on the ICHG pin. The charge current is set as:

 $I_{ICHG} = K_{ICHG}/R_{ICHG}$  (1)

Input current limit must be programmed to a value within a range of 500 mA to 3200 mA with a pull-down resistor on the ILIM pin. The input current limit is set as:

 $I_{\text{INDPM}} = K_{\text{IUM}}/R_{\text{IUM}}$  (2)

The battery regulation voltage is programmed with a pull-down resistor on the VSET pin as follows:

- $R_{VSET}$  > 50 k $\Omega$  (float pin):  $V_{REG}$  = 4.20-V
- $R_{VSET}$  < 500 Ω (short pin):  $V_{REG}$  = 4.35-V
- 5kΩ < R<sub>VSET</sub> < 25 kΩ: V<sub>REG</sub> = 4.10-V

#### **Table 3. Standalone Device Configuration (continued)**

If a fault is detected, the STAT pin will blink at 1 Hz. STAT pin will stop blinking when the fault goes away. All faults will be reset upon adapter re-connection. A boost mode fault will be cleared either by adapter reconnection or toggling of the OTG pin.

#### **9.3.6 Power Path Management**

The device accommodates a wide range of input sources such as USB, wall adapter, or car charger. The device provides automatic power path selection to supply the system (SYS) from the input source (VBUS), battery (BAT), or both.

#### *9.3.6.1 Narrow VDC Architecture*

When the battery is below the minimum system voltage setting, the BATFET operates in linear mode (LDO mode), and the system is typically 180 mV above the minimum system voltage setting. As the battery voltage rises above the minimum system voltage, the BATFET is fully on and the voltage difference between the system and battery is the  $V_{DS}$  of the BATFET.

When battery charging is disabled and above the minimum system voltage setting or charging is terminated, the system is always regulated at typically 50 mV above the battery voltage.

**Figure 9. System Voltage vs Battery Voltage**

### *9.3.6.2 Dynamic Power Management*

To meet the maximum current limit in the USB specification and avoid overloading the adapter, the device features Dynamic Power Management (DPM), which continuously monitors the input current and input voltage. When input source is overloaded, either the current exceeds the input current limit (IINDPM) or the voltage falls below the input voltage limit (VINDPM). The device then reduces the charge current until the input current falls below the input current limit or the input voltage rises above the input voltage limit.

When the charge current is reduced to zero, but the input source is still overloaded, the system voltage starts to drop. Once the system voltage falls below the battery voltage, the device automatically enters the supplement mode where the BATFET turns on and the battery starts discharging so that the system is supported from both the input source and battery.

[Figure](#page-20-0) 10 shows the DPM response with 9-V/1.2-A adapter, 3.2-V battery, 2.8-A charge current and 3.5-V minimum system voltage setting.

**Figure 10. DPM Response**

#### <span id="page-20-2"></span><span id="page-20-0"></span>*9.3.6.3 Supplement Mode*

When the system voltage falls below the battery voltage, the BATFET turns on and the BATFET gate is regulated so that the minimum BATFET  $V_{DS}$  stays at 30 mV when the current is low. This prevents oscillation from entering and exiting the supplement mode.

As the discharge current increases, the BATFET gate is regulated with a higher voltage to reduce  $R_{DSON}$  until the BATFET is in full conduction. At this point onwards, the BATFET  $V_{DS}$  linearly increases with discharge current. shows the V-I curve of the BATFET gate regulation operation. The BATFET turns off to exit supplement mode when the battery is below battery depletion threshold.

#### **9.3.7 Battery Charging Management**

The device charges 1-cell Li-Ion battery with up to 3.0-A charge current for high capacity tablet battery. The 19.5 mΩ BATFET improves charging efficiency and minimizes the voltage drop during discharging.

#### *9.3.7.1 Autonomous Charging Cycle*

<span id="page-20-1"></span>When battery charging is enabled (CE pin is LOW), the device autonomously completes a charging cycle. The device default charging parameters are listed in [Table](#page-20-1) 4.

#### **Table 4. Charging Parameter Default Setting**

A new charge cycle starts when the following conditions are valid:

- Converter starts
- Battery charging is enabled  $(\overline{CE}$  is low)
- No thermistor fault on TS.
- No safety timer fault

The device automatically terminates the charging cycle when the charging current is below the termination threshold, the battery voltage is above the recharge threshold, and the device is not in DPM mode or thermal regulation. When a fully charged battery is discharged below recharge threshold , the device automatically starts a new charging cycle. After the charge is done, toggle  $\overline{CE}$  pin will initiate a new charging cycle. Adapter removal and replug will also restart a charging cycle.

The STAT output indicates the charging status: charging (LOW), charging complete or charge disable (HIGH) or charging fault (blinking).

#### *9.3.7.2 Battery Charging Profile*

The device charges the battery in five phases: battery short, preconditioning, constant current, constant voltage and top-off trickle charging. At the beginning of a charging cycle, the device checks the battery voltage and regulates current and voltage accordingly.

**Figure 11. Battery Charging Profile**

#### *9.3.7.3 Charging Termination*

The device terminates a charge cycle when the battery voltage is above the recharge threshold, and the current is below termination current. After the charging cycle is completed, the BATFET turns off. The STAT is asserted HIGH to indicate charging done. The converter keeps running to power the system, and BATFET can turn on again to engage [Supplement](#page-20-2) Mode.

If the device is in IINDPM/VINDPM regulation, or thermal regulation, the actual charging current will be less than the termination value. In this case, termination is temporarily disabled.

When termination occurs, STAT pin goes HIGH.

Top-off timer gets reset at one of the following conditions:

- 1. Charge disable to enable
- 2. Charger enters termination

#### *9.3.7.4 Thermistor Qualification*

The device provides a single thermistor input for battery temperature monitoring.

#### **9.3.7.4.1 JEITA Guideline Compliance During Charging Mode (BQ25616J)**

To improve the safety of charging Li-ion batteries, the JEITA guideline was released on April 20, 2007. The guideline emphasized the importance of avoiding a high charge current and high charge voltage at certain low and high temperature ranges.

To initiate a charge cycle, the voltage on TS pin, as a percentage of  $V_{REGN}$ , must be within the  $V_{T1-FALL}$  to  $V_{T5-RISE%}$  thresholds. If the TS voltage percentage exceeds the T1-T5 range, the controller suspends charging, a TS fault is reported and waits until the battery temperature is within the T1 to T5 range.

At cool temperature (T1-T2), JEITA recommends the charge current to be reduced to 20% of  $I_{CHG}$ . At warm temperature (T3-T5), JEITA recommends charge voltage less than 4.1-V.

**Figure 12. JEITA Profile (BQ25616J)**

**RUMENTS** 

[Equation](#page-23-0) 3 through [Equation](#page-23-1) 4 describe how to calculate resistor divider values on Ts pin.

**Figure 13. TS Pin Resistor Network**

<span id="page-23-0"></span>
$$
RT1 = \frac{\frac{1}{V_{T1}\%} - 1}{\frac{1}{R_{T2}} + \frac{1}{R_{NTC,T1}}} \tag{3}
$$
\n
$$
RT2 = \frac{R_{NTC,T1} \times R_{NTC,T5} \times \left(\frac{1}{V_{T5}\%} - \frac{1}{V_{T1}\%}\right)}{R_{NTC,T1} \times \left(\frac{1}{V_{T1}\%} - 1\right) - R_{NTC,T5} \times \left(\frac{1}{V_{T5}\%} - 1\right)} \tag{4}
$$

<span id="page-23-1"></span>In the equations above,  $R_{NTC, T1}$  is NTC thermistor resistance value at temperature T1 and  $R_{NTC, T5}$  is NTC thermistor resistance values at temperature T5. Select 0°C to 60°C range for Li-ion or Li-polymer battery then

- $R_{NTC,T1} = 27.28 KΩ (0°C)$
- $R_{NTC, T5}$  = 3.02 KΩ (60°C)
- $RT1 = 5.3 K\Omega$
- $RT2 = 31.14$  KΩ

#### **9.3.7.4.2 Hot/Cold Temperature Window During Charging Mode (BQ25616)**

The BQ25616 provides simple Hot/Cold window T1-T3 with V<sub>REG</sub> and I<sub>CHG</sub> set on the pins. When RT1 is 5.3 K $\Omega$ and RT2 is 31.14 K $\Omega$ , T1 is 0°C and T3 is 45°C.

**Figure 14. Hot/Cold Profile (BQ25616)**

#### **9.3.7.4.3 Boost Mode Thermistor Monitor During Battery Discharge Mode**

For battery protection during boost mode, the device monitors the battery temperature to be within the  $V_{BCOLD}$ and V<sub>BHOT</sub> thresholds. When RT1 is 5.3 KΩ and RT2 is 31.14 KΩ, T<sub>BCOLD</sub> default is -19.5°C and T<sub>BHOT</sub> default is 64°C. When temperature is outside of the temperature thresholds, the boost mode is suspended.

## *9.3.7.5 Charging Safety Timer*

The device has a built-in safety timer to prevent extended charging cycle due to abnormal battery conditions. The safety timer is 2 hours when the battery is below  $V_{BATLOWV}$  threshold and 10 hours when the battery is higher than V<sub>BATLOWV</sub> threshold. When the safety timer expires, STAT pin is blinking at 1 Hz to report a safety timer expiration fault.

During IINDPM/VINDPM regulation, or thermal regulation, the safety timer counts at a half clock rate, because the actual charge current is likely below the setting. For example, if the charger is in input current regulation throughout the whole charging cycle, and the safety time is set to 10 hours, the safety timer will expire in 20 hours.

During faults of BAT\_FAULT, NTC\_FAULT that lead to charging suspend, safety timer is suspended as well. Once the fault goes away, timer resumes. If user stops the current charging cycle, and start again, timer gets reset (toggle CE pin).

## **9.3.8 Status Outputs (PG, STAT)**

## *9.3.8.1 Power Good Indicator (PG Pin)*

The  $\overline{PG}$  pin goes LOW to indicate a good input source when:

- $V_{VBUS}$  above  $V_{VBUS}$  uvlo
- $V_{VBUS}$  above battery (not in sleep)
- $V_{VBUS}$  below  $V_{ACOV}$  threshold
- $V_{VBUS}$  above  $V_{POORSRC}$  (typical 3.8 V) when  $I_{BADSRC}$  (typical 30 mA) current is applied (not a poor source)

• Completed Input Source Type Detection (IINDPM [Threshold\)](#page-16-2)

### *9.3.8.2 Charging Status Indicator (STAT)*

The device indicates charging state on the open drain STAT pin. The STAT pin can drive LED.

#### **Table 6. STAT Pin State**

#### **9.3.9 Protections**

#### *9.3.9.1 Input Current Limit*

The device's ILIM pin is to program maximum input current when D+/D– detection identifies an unknown adaptor plugged in. The maximum input current is set by a resistor from ILIM pin to ground as:

$$
I_{\text{INDPM}} = \frac{K_{\text{ILIM}}}{R_{\text{ILIM}}}
$$

(5)

#### *9.3.9.2 Voltage and Current Monitoring in Buck Mode*

#### **9.3.9.2.1 Input Over-Voltage Protection (ACOV)**

This device integrates the functionality of an over-voltage protector. The device can be paired with an external Nchannel FET to block input voltages in excess of VBUS rating. For correct operation, connect the cathode of the body diode to VAC node. Back-to-back body diodes between VAC and VBUS are not recommended and will prevent correct operation. The input voltage is sensed via the VAC pin and the ACDRV pin is used to control the external FET gate for protection. The default OVP threshold is 14.2-V. The ACOV circuit has a reaction time of 130-ns (typical) to turn off the external ACFET. Note that turning off the external ACFET will take longer and depends on its gate capacitance. In addition to turning off the external ACFET, an ACOV event will immediately stop converter switching whether in buck or boost mode. The device will automatically resume normal operation once the input voltage drops back below the OVP threshold. During ACOV, REGN LDO is on, and the device doesn't enter HIZ mode.

#### **9.3.9.2.2 System Over-Voltage Protection (SYSOVP)**

The charger device clamps the system voltage during a load transient so that the components connected to the system are not damaged due to high voltage.  $\rm V_{\rm{SYS\_OVP}}$  threshold is about 300-mV above battery regulation voltage when battery charging is terminated. Upon SYSOVP, converter stops switching immediately to clamp the overshoot. The charger pulls 30-mA  $I_{SYS\ LAD}$  discharge current to bring down the system voltage.

#### *9.3.9.3 Voltage and Current Monitoring in Boost Mode*

#### **9.3.9.3.1 Boost Mode Over-Voltage Protection**

When the PMID voltage rises above regulation the target and exceeds  $V_{\text{BST OVP}}$ , the device stops switching immediately and the device exits boost mode after the boost mode OVP lasts for 12 ms. Meanwhile, if VAC (and VBUS when shorted to VAC) voltage exceed  $V_{ACOV}$ , the device will exit boost mode as well.

#### *9.3.9.4 Thermal Regulation and Thermal Shutdown*

#### **9.3.9.4.1 Thermal Protection in Buck Mode**

Besides the battery temperature monitor on TS pin, the device monitors the internal junction temperature T<sub>J</sub> to avoid overheating the chip and limits the IC junction temperature in buck mode. When the internal junction temperature exceeds thermal regulation limit (110°C), the device lowers down the charge current. During thermal regulation, the actual charging current is usually below the programmed battery charging current. Therefore, termination is disabled, the safety timer runs at half the clock rate.

Additionally, the device has thermal shutdown to turn off the converter and BATFET when IC surface temperature exceeds  $T_{\text{SHUT}}$  150°C. The BATFET and converter is enabled to recover when IC temperature is 130ºC.

#### **9.3.9.4.2 Thermal Protection in Boost Mode**

Besides the battery temperature monitor on TS pin, The device monitors the internal junction temperature to provide thermal shutdown during boost mode. When IC junction temperature exceeds  $T<sub>SHUT</sub>$  150°C, the boost mode is disabled . When IC junction temperature is below 145ºC, the host can re-enable boost mode.

#### *9.3.9.5 Battery Protection*

#### **9.3.9.5.1 Battery Over-Voltage Protection (BATOVP)**

The battery over-voltage limit is clamped at 4% above the battery regulation voltage. When battery over-voltage occurs, the charger device immediately stops switching.

#### **9.3.9.5.2 Battery Over-Discharge Protection**

When battery is discharged below  $V_{BAT}$   $_{DPL}$   $_{FALL}$ , the BATFET will latch off to protect battery from over discharge. To recover from over-discharge latch-off, an input source plug-in is required at VAC/VBUS.

#### **9.3.9.5.3 System Over-Current Protection**

 $I_{SYS~OCP~Q4}$  sets battery discharge current limit. Once  $I_{BAT} > I_{SYS~OCP~Q4}$ , charger will latch off Q4 and put the device into ship mode. All methods to exit ship mode are valid to bring the part out of Q4 latch off.

#### <span id="page-26-0"></span>**9.4 Device Functional Modes**

The BQ25616/616J is a standalone device and therefore does not have  $I<sup>2</sup>C$  functions.

Texas **NSTRUMENTS** 

## <span id="page-27-0"></span>**10 Application and Implementation**

#### **NOTE**

information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### <span id="page-27-1"></span>**10.1 Application Information**

A typical application consists of the device configured as a stand-alone Power Path management device and a single cell battery charger for Li-Ion and Li-polymer batteries used in a wide range of smart phones and other portable devices. It integrates an input reverse-block FET (RBFET, Q1), high-side switching FET (HSFET, Q2), low-side switching FET (LSFET, Q3), and battery FET (BATFET Q4) between the system and battery. The device also integrates a bootstrap diode for the high-side gate drive.

External ACFET is optional. When external OVP is not used, short the VBUS and VAC pins and allow ACDRV pin to float.

### <span id="page-27-2"></span>**10.2 Typical Applications**

#### **10.2.1 BQ25616/616J Application without External OVP**

## **Typical Applications (continued)**

### <span id="page-28-0"></span>*10.2.1.1 Design Requirements*

For this design example, use the parameters shown in the table below.

#### **Table 7. Design Parameters**

#### <span id="page-28-1"></span>*10.2.1.2 Detailed Design Procedure*

#### **10.2.1.2.1 Inductor Selection**

The 1.5-MHz switching frequency allows the use of small inductor and capacitor values to maintain an inductor saturation current higher than the charging current ( $I_{CHG}$ ) plus half the ripple current ( $I_{RIPPE}$ ):

$$
I_{\text{SAT}} \geq I_{\text{CHG}} + (1/2) I_{\text{RIPPLE}} \tag{6}
$$

The inductor ripple current depends on the input voltage (V<sub>VBUS</sub>), the duty cycle (D = V<sub>BAT</sub>/V<sub>VBUS</sub>), the switching frequency  $(f_S)$  and the inductance (L).

$$
I_{RIPPLE} = \frac{V_{IN} \times D \times (1 - D)}{fs \times L}
$$
 (7)

The maximum inductor ripple current occurs when the duty cycle (D) is 0.5 or approximately 0.5. Usually inductor ripple is designed in the range between 20% and 40% maximum charging current as a trade-off between inductor size and efficiency for a practical design.

#### **10.2.1.2.2 Input Capacitor and Resistor**

Design input capacitance to provide enough ripple current rating to absorb input switching ripple current. The worst case RMS ripple current is half of the charging current when duty cycle is 0.5. If the converter does not operate at 50% duty cycle, then the worst case capacitor RMS current  $I_{\text{C}N}$  occurs where the duty cycle is closest to 50% and can be estimated using .

$$
I_{\text{CIN}} = I_{\text{CHG}} \times \sqrt{D \times (1 - D)}
$$
\n(8)

Low ESR ceramic capacitor such as X7R or X5R is preferred for input decoupling capacitor and should be placed to the drain of the high-side MOSFET and source of the low-side MOSFET as close as possible. Voltage rating of the capacitor must be higher than normal input voltage level. A rating of 25-V or higher capacitor is preferred for 12-V input voltage. Capacitance of minimum 10 μF is suggested for typical of 3-A charging current.

During high current output over 700 mA in boost mode, a 10 kΩ pull-down resistor on VBUS is recommended to keep VBUS low in case Q1 RBFET leakage gets high.

#### **10.2.1.2.3 Output Capacitor**

Ensure that the output capacitance has enough ripple current rating to absorb the output switching ripple current. shows the output capacitor RMS current  $I_{\text{COLIT}}$  calculation.

$$
I_{\text{COUT}} = \frac{I_{\text{RIPPLE}}}{2 \times \sqrt{3}} \approx 0.29 \times I_{\text{RIPPLE}}
$$

The output capacitor voltage ripple can be calculated as follows:

$$
\Delta V_{\rm O} = \frac{V_{\rm OUT}}{8LCfs^2} \left(1 - \frac{V_{\rm OUT}}{V_{\rm IN}}\right)
$$
 (10)

At certain input and output voltage and switching frequency, the voltage ripple can be reduced by increasing the output filter LC.

The charger device has internal loop compensation optimized for >10-μF ceramic output capacitance. The preferred ceramic capacitor is 10-V rating, X7R or X5R.

## <span id="page-36-0"></span>**11 Power Supply Recommendations**

In order to provide an output voltage on SYS, the battery charger requires a power supply between 4-V and 13.5- V input with at least 100-mA current rating connected to VBUS and a single-cell Li-Ion battery with battery voltage greater than V<sub>BAT\_UVLOZ</sub> connected to BAT. The source current rating needs to be at least 3-A in order for the buck converter of the charger to provide maximum output power to SYS.

## <span id="page-36-1"></span>**12 Layout**

## <span id="page-36-2"></span>**12.1 Layout Guidelines**

The switching node rise and fall times should be minimized for minimum switching loss. Proper layout of the components to minimize high frequency current path loop (see [Figure](#page-36-4) 37) is important to prevent electrical and magnetic field radiation and high frequency resonant problems. Follow this specific order carefully to achieve the proper layout.

- 1. Place input capacitor as close as possible to PMID pin and GND pin connections and use shortest copper trace connection or GND plane. Add 1 nF small size (such as 0402 or 0201) decoupling cap for high frequency noise filter and EMI improvement.
- 2. Place inductor input pin to SW pin as close as possible. Minimize the copper area of this trace to lower electrical and magnetic field radiation but make the trace wide enough to carry the charging current. Do not use multiple layers in parallel for this connection. Minimize parasitic capacitance from this area to any other trace or plane.
- 3. Put output capacitor near to the inductor and the device. Ground connections need to be tied to the IC ground with a short copper trace connection or GND plane.
- 4. Route analog ground separately from power ground. Connect analog ground and connect power ground separately. Connect analog ground and power ground together using thermal pad as the single ground connection point. Or using a  $0$ -Ω resistor to tie analog ground to power ground.
- 5. Use single ground connection to tie charger power ground to charger analog ground. Just beneath the device. Use ground copper pour but avoid power pins to reduce inductive and capacitive noise coupling.
- 6. Place decoupling capacitors next to the IC pins and make trace connection as short as possible.
- 7. It is critical that the exposed thermal pad on the backside of the device package be soldered to the PCB ground. Ensure that there are sufficient thermal vias directly under the IC, connecting to the ground plane on the other layers.
- 8. Ensure that the number and sizes of vias allow enough copper for a given current path.

[SLYZ022](http://www.ti.com/lit/pdf/SLYZ022) — *TI Glossary*.

This glossary lists and explains terms, acronyms, and definitions.

## <span id="page-39-0"></span>**14 Mechanical, Packaging, and Orderable Information**

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

## **PACKAGING INFORMATION**

**(1)** The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

<sup>(2)</sup> RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (CI) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

**(3)** MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

**(4)** There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

**(5)** Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

<sup>(6)</sup> Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

# PLASTIC QUAD FLATPACK NO-LEAD

## THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

RTW (S-PWQFN-N24)

PLASTIC QUAD FLATPACK NO-LEAD

**NOTES:**
