

# CMOS $\mu$ P-Compatible, 5 $\mu$ s, 8-Bit ADCs

MAX165/MAX166

## General Description

The MAX165/MAX166 are high-speed (5 $\mu$ s) microprocessor ( $\mu$ P)- compatible, 8-bit ADCs with track/hold (T/H). The T/H function allows full-scale signals up to 50kHz (386mV/ $\mu$ s slew rate) to be acquired and digitized accurately. Both ADCs use a successive approximation technique to achieve fast conversions and low power dissipation. The MAX165/MAX166 operate with a +5V supply and an internal or external +1.23V reference, and accept single-ended (MAX165) or differential (MAX166) voltages ranging from 0V to 2VREF.

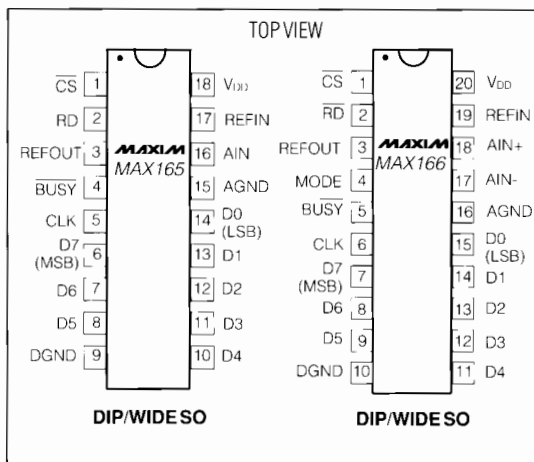

The MAX165/MAX166 are easily interfaced to all popular 8-bit  $\mu$ Ps through standard  $\overline{CS}$  and  $\overline{RD}$  control signals. These signals control the start of conversions and data access. A  $\overline{BUSY}$  signal indicates the beginning and end of conversions. Since all the data outputs are latched and three-state buffered, the MAX165/MAX166 can be directly tied to a  $\mu$ P data bus or system input/output port.

The MAX165 is a plug-in replacement for the MX7575, with the addition of an internal 1.23V reference. For applications that require a differential analog input and an internal reference, the MAX166 is recommended.

## Applications

- Digital-Signal Processing
- High-Speed Data Acquisition
- Telecommunications
- Audio Systems
- High-Speed Servo Loops
- Low-Power Data Loggers

## Pin Configurations

## Features

- ◆ 5 $\mu$ s Conversion Time
- ◆ Built-In Track/Hold
- ◆  $\pm 1$ LSB Max Total Unadjusted Error
- ◆ 50kHz Signal Bandwidth
- ◆ Internal 1.23V Bandgap Reference and Buffer
- ◆ Single +5V Supply Operation
- ◆ 8-Bit  $\mu$ P Interface
- ◆ 100ns Data-Access Time
- ◆ 15mW Typ Power Consumption
- ◆ Small Footprint Packages
- ◆ Plug-In Upgrade to the MX7575 (MAX165)

## Detailed Description

### Converter Operation

The MAX165/MAX166 use the successive approximation technique to convert an unknown analog input voltage to an 8-bit digital output code (see *Functional Diagrams*). The MAX165/MAX166 sample the input voltage on an internal capacitor once at the beginning of the conversion, (see *Track/Hold* section). The DAC is initially set to half scale, and the comparator determines whether the input signal is larger or smaller than half scale. If the input is larger, the DAC most significant bit (MSB) is kept; if it is smaller, the MSB is dropped. At the end of each comparison phase, the successive approximation register (SAR) stores the results of the previous decisions and determines the next trial bit. This information is loaded into the DAC after each decision. As the conversion proceeds, the analog input is approximated more closely as it is compared to the combined previous DAC bits and a new DAC trial bit. After 8 comparison cycles, the 8 bits stored in the SAR are latched into the output latches. At the end of the conversion, the  $\overline{BUSY}$  signal goes high, and the data in the output latches is ready for  $\mu$ P access. Furthermore, the DAC is reset to half scale in preparation for the next conversion.

### Microprocessor Interface

The  $\overline{CS}$  and  $\overline{RD}$  logic inputs are used to initiate conversions and to access data from the devices. The MAX165/

## Pin Description

MAX165/MAX166

PIN		NAME	FUNCTION
MAX165	MAX166		
1	1	$\overline{CS}$	CHIP SELECT Input. $\overline{CS}$ must be low for the device to be selected, or to recognize the $\overline{RD}$ input.
2	2	$\overline{RD}$	READ Input. $\overline{RD}$ must be low to access data. $\overline{RD}$ is also used to start conversions. See the <i>Digital Interface</i> section.
3	3	REFOUT	Output of the internal 1.23V bandgap reference
	4	MODE	MODE (MAX166). Mode = low puts the ADC into asynchronous-conversion mode. MODE has to be tied high for synchronous-conversion mode and ROM interface mode.
4	5	$\overline{BUSY}$	BUSY Output. $\overline{BUSY}$ going low indicates the start of a conversion. $\overline{BUSY}$ going high indicates the end of a conversion.
5	6	CLK	External Clock Input/Internal Oscillator Pin for frequency setting RC components.
6	7	D7 (MSB)	Three-State Data Output, bit 7 (MSB)

PIN		NAME	FUNCTION
MAX165	MAX166		
7	8	D6	Three-State Data Output, bit 6
8	9	D5	Three-State Data Output, bit 5
9	10	DGND	Digital Ground
10	11	D4	Three-State Data Output, bit 4
11	12	D3	Three-State Data Output, bit 3
12	13	D2	Three-State Data Output, bit 2
13	14	D1	Three-State Data Output, bit 1
14	15	D0 (LSB)	Three-State Data Output, bit 0 (LSB)
15	16	AGND	Analog Ground
16		AIN	Analog Input (single-ended with respect to AGND) 0V to 2VREF input range
	17	AIN	Negative Analog Input - differential (MAX166)
	18	AIN+	Positive Analog Input - differential (MAX166)
17	19	REFIN	Reference Input +1.23V nominal
18	20	VDD	Power-Supply Voltage +5V nominal

MAX166 have two common interface modes that will be referred to as slow-memory interface mode and ROM interface mode. In addition, the MAX166 has an asynchronous conversion mode (MODE pin = low) where continuous conversions are performed. In the slow-memory interface mode,  $\overline{CS}$  and  $\overline{RD}$  are taken low to start a conversion and remain low until the end of the conversion, at which time data is updated. This mode is designed for  $\mu$ Ps that can be forced into a wait state. In ROM interface mode, however, the  $\mu$ P is not forced into a wait state. A conversion is started by taking  $\overline{CS}$  and  $\overline{RD}$  low, and data from the previous conversion is read. At the end of the most recent conversion, the  $\mu$ P executes a READ instruction and starts another conversion.

### Slow-Memory Interface Mode

Figure 3 shows the timing diagram for slow-memory interface mode. This mode is used with  $\mu$ Ps that have a wait state capability of at least 5 $\mu$ s (such as the 8085A), where a READ instruction is extended to accommodate slow-memory devices. A conversion is started by ex-

ecuting a memory READ to the device (taking  $\overline{CS}$  and  $\overline{RD}$  low). The  $\overline{BUSY}$  signal (which is connected to the  $\mu$ P READY input) then goes low and forces the  $\mu$ P into a wait state. The T/H, which has been tracking the analog input signal, holds the signal on the third falling clock edge after  $\overline{RD}$  goes low (Figure 12). At the end of the conversion,  $\overline{BUSY}$  returns high, the output latches, and buffers are updated with the new conversion results. The  $\mu$ P then completes the memory READ by acquiring this new data.

Figure 3. Slow-Memory Interface Mode Timing Diagram

## CMOS $\mu$ P-Compatible 5 $\mu$ s, 8-Bit ADCs

The MAX165/MAX166's fast conversion time ensures that the  $\mu$ P is not forced into a wait state for too long. Faster versions of many  $\mu$ Ps, including the 8085A-2, test the status of the READY input right after the start of an instruction cycle. Therefore, for the MAX165/MAX166 to effectively place the  $\mu$ P in a wait state, their BUSY output should go low very early in the cycle. When using the 8085A-2, the earliest possible indication of an upcoming READ operation is provided by the S0 status signal. Thus, S0 (which is low for a READ cycle) should be connected to the RD input of the MAX165/MAX166. Figure 4 shows the connection diagram for the 8085A-2 to the MAX165/MAX166 in slow-memory interface mode.

### ROM Interface Mode

Figure 5 shows the timing diagram for ROM interface mode. In this mode, the  $\mu$ P does not need to be placed in a wait state. A conversion is started with a READ instruction (RD and CS go low), and old data is accessed. The BUSY signal then goes low to indicate the start of a conversion. As before, the T/H acquires the signal on the third falling clock edge after RD goes low. At the end of conversion (BUSY going high), another READ instruction always accesses the new data and normally starts a second conversion. However, if RD and CS go low within one external clock period of BUSY going high, the second

conversion is not started. For correct operation in this mode, RD and CS should not go low before BUSY returns high.

Figures 6 and 7 show the connection diagrams for interfacing the MAX165/MAX166 in ROM interface mode. Figure 6 shows the connection diagram to the 6502/6809  $\mu$ Ps, and Figure 7 shows interfacing to the Z-80.

Due to their fast interface timing, the MAX165/MAX166 will interface to the TMS32010 running at up to 18MHz. Figure 8 shows the connection diagram to the TMS32010. In this interface, the MAX165/MAX166 are mapped as a port address. A conversion is initiated by using an IN A and a PA instruction, and the conversion result is placed in the TMS32010 accumulator.

### Asynchronous Conversion Mode (MAX166)

Tying the MODE pin low places the MAX166 into a continuous-conversion mode. The RD and CS inputs are only used for reading data from the converter. Figure 9 shows the timing diagram for this mode of operation, and Figure 10 shows the connection diagram of the converter to the 8085A. In this mode, the MAX166 appears like a ROM to the  $\mu$ P, in that data can be accessed independently of the clock. The output latches are normally

Figure 4. MAX165/MAX166 to 8085A-2 Slow-Memory Interface

## CMOS $\mu$ P-Compatible, 5 $\mu$ s, 8-Bit ADCs

**MAX165/MAX166**

updated on the rising edge of  $\overline{\text{BUSY}}$ . But, if  $\overline{\text{CS}}$  and  $\overline{\text{RD}}$  are low when  $\overline{\text{BUSY}}$  goes high, the data latches are not updated until one of these inputs returns high. Additionally, the MAX166 stops converting and  $\overline{\text{BUSY}}$  stays high until  $\overline{\text{RD}}$  or  $\overline{\text{CS}}$  goes high. This mode of operation allows a simple  $\mu$ P interface.

### Microprocessor Interface For Signal Acquisition

Many applications require sampling of the input signal at equal intervals to minimize errors caused by sampling uncertainty or jitter. To achieve this with the previously discussed interfaces, the user must match software delays or count the number of elapsed clock cycles. This becomes difficult in interrupt driven systems where the uncertainty in interrupt servicing delays is another complicating factor.

The solution is to use a real-time clock to control the start of a conversion. This should be synchronous with the clock input to the ADC (both should be derived from the same source) because the sampling instants occur three clock cycles after  $\overline{\text{CS}}$  and  $\overline{\text{RD}}$  go low. Therefore, the sampling instants occur at exactly equal intervals if the conversions are started at equal intervals. In this scheme, the output data is fed into a FIFO latch, which allows the  $\mu$ P to access data at its own rate. This guarantees that data is not read from the ADC in the middle of a conversion. If data is read from the ADC during a conversion, the conversion in progress may be disturbed, but the accessed data that belonged to the previous conversion will be correct.

The T/H starts holding the input on the third falling edge of the clock after  $\overline{\text{CS}}$  and  $\overline{\text{RD}}$  go low. If  $\overline{\text{CS}}$  and  $\overline{\text{RD}}$  go low within 20ns of a falling clock edge, the ADC may or may not consider this falling edge as the first of the three edges that determine the sampling instant. Therefore, the  $\overline{\text{CS}}$  and  $\overline{\text{RD}}$  should not be allowed to go low within this period when sampling accuracy is required.

### Track/Hold

The T/H consists of a sampling capacitor and a switch to capture the input signal. The simplified diagram of this block is shown in Figure 11. At the beginning of the conversion, switch S1 is closed, and the input signal is tracked. The input signal is held (switch S1 opens) on the third falling edge of clock after  $\overline{\text{CS}}$  and  $\overline{\text{RD}}$  go low (Figure 12). This allows a minimum of two clock cycles for the input capacitor to be charged to the input voltage through the switch resistance. The time required for the hold capacitor to settle to  $\pm 1/4\text{LSB}$  is typically 7ns. Therefore, the input signal is allowed ample time to settle before it is acquired by the T/H. When a conversion ends, switch S1 closes, and the input signal is tracked.

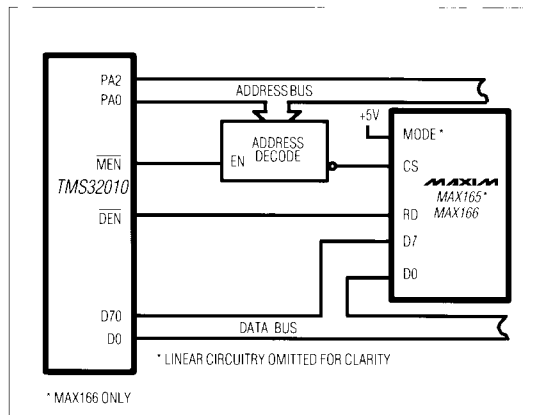

Figure 8. MAX165/MAX166 to TMS32010 ROM Interface

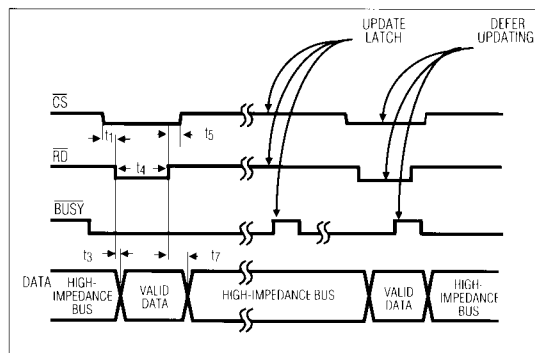

Figure 9. MAX166 Asynchronous-Conversion Mode Timing Diagram

Figure 10. MAX166 to 8085A Asynchronous-Conversion Mode Interface

## CMOS $\mu$ P-Compatible $5\mu$ s, 8-Bit ADCs

The T/H can acquire signals with slew rates of up to  $386\text{mV}/\mu\text{s}$  (or equivalently a  $50\text{kHz}$  sine wave with  $2.46\text{V}_{\text{p-p}}$  amplitude). Figure 13 shows the signal-to-noise ratio (SNR) versus input frequency for the ADC. The SNR plot is generated at a sampling rate of  $200\text{kHz}$  using sinusoidal inputs with a  $2.46\text{V}_{\text{p-p}}$  amplitude. The reconstructed sine wave is passed through a  $50\text{kHz}$ , 8th-order Chebyshev filter. The improvement in SNR at high frequencies is due to the filter cutoff.

The switching nature of the analog input results in transient currents that charge the T/H's input capacitance. Keep the driving source impedance low (below  $2\text{k}\Omega$ ) so the T/H's settling characteristics are not degraded. A low driving impedance also minimizes undesirable noise pick-up and reduces DC errors caused by transient currents at the analog input. As with any ADC, it is important to keep external noise sources to a minimum during a conversion. Keep the data bus as quiet as possible during a conversion, especially when the T/H is making a transition to hold mode.

Device accuracy may degrade slightly when conversion times are significantly longer than  $5\mu\text{s}$ , as shown in Figure 14. This degradation is due to the charge that is lost from the hold capacitor in the presence of small on-chip leakage currents.

### Differential Input (MAX166)

The MAX166 converts differential inputs [(AIN+) - (AIN-)] in the  $0\text{V}$  to  $2\text{V}_{\text{REF}}$  range. This can be especially useful in single-supply applications where the output swing requirements on the input amplifier are reduced. For example, if AIN- is tied to the reference output of the MAX166, the voltage swing on AIN+ must fall in the  $1.23\text{V}$  to  $3.69\text{V}$  range. Furthermore, the differential capability allows the converter to reject low-frequency common-mode signals.

The voltage at AIN+ is sampled at the beginning of the conversion and is referenced to AIN- during the conversion. Therefore, it is essential that the voltage on AIN- be relatively constant with respect to AGND during the conversion, otherwise conversion errors will result. If the AIN- input changes by a small voltage during the conversion,

Figure 11. MAX165/MAX166 Equivalent Input Circuit

the conversion result can show an error in the same amount. For example, if the input has a  $60\text{Hz}$  common-mode component of  $0.5\text{V}$  with respect to AGND, an error of less than  $0.1\text{LSB}$  is incurred during the  $5\mu\text{s}$  conversion. Conversion errors increase with higher frequency or higher amplitude common-mode signals.

### Reference Input

This ADC's high speed can be partially attributed to its DAC's "inverted-voltage output" topography. This topography provides low offset and gain errors and fast settling times. The input current to the DAC, however, is not constant. During a conversion, as different DAC codes are tried, the DAC's DC impedance can vary between  $6\text{k}\Omega$  and  $18\text{k}\Omega$ . Furthermore, when the DAC codes change, small amounts of transient current are drawn from the reference input. These characteristics require a low DC and AC driving impedance for the reference circuitry to minimize conversion errors.

Figure 15 shows the external reference circuitry recommended for driving the reference input of the MAX165/MAX166. The decoupling capacitors are necessary to provide a low AC source impedance.

Figure 15. External Reference Circuit

## Internal Reference

The MAX165/MAX166 have an internal 1.23V bandgap reference and buffer suitable for driving the reference input of the ADC. As discussed before, the reference input requires a low DC and AC driving impedance.

The reference buffer requires a 4.7 $\mu$ F low-ESR capacitor (tantalum or aluminum with additional 0.1 $\mu$ F ceramic) for compensation and to achieve low-AC impedance. If this capacitor is omitted, oscillations can occur on the REFOUT pin. If the user opts for an external reference, the REFOUT pin can be tied to  $V_{DD}$  to disable the internal reference.

## Internal/External Clock

The MAX165/MAX166 can be run either with an externally applied clock or with their internal clock. In either case, the signal appearing at the clock pin is internally divided by two to provide an internal clock signal that is relatively insensitive to the input clock duty cycle. Therefore, a single conversion takes 20 input clock cycles, which corresponds to 10 internal clock cycles.

### Internal Clock

The internal oscillator frequency is set by an external capacitor,  $C_{CLK}$ , and an external resistor,  $R_{CLK}$ , which are connected as shown in Figure 16a. During a conversion, a sawtooth waveform is generated on the CLK pin by charging  $C_{CLK}$  through  $R_{CLK}$  and discharging it through an internal switch. At the end of a conversion, the internal oscillator is shut down by clamping the CLK pin to  $V_{DD}$  through an internal switch. The circuit for the internal oscillator can be easily overdriven with an external clock source.

The internal oscillator provides a convenient clock source for the MAX165/MAX166. Typical conversion times versus temperature for the recommended  $R_{CLK}$  and  $C_{CLK}$  combination are shown in Figure 17. Due to process variations, the oscillation frequency for this  $R_{CLK}$ ,  $C_{CLK}$  combination may vary by as much as  $\pm 50\%$  from the nominal value shown in Figure 17. Therefore, an external clock should be used in the following situations:

1. Applications which require the conversion time to be within 50% of the minimum conversion time for the specified accuracy (5 $\mu$ s).
2. Applications in which time-related software constraints cannot accommodate conversion time differences, which may occur from unit to unit or over temperature for a given device.

### External Clock

The CLK input of the MAX165/MAX166 may be driven directly by a 74HC or 4000B series buffer (e.g., 4049) or an LS TTL with a 5.6k $\Omega$  pullup resistor. At the end of a

## CMOS $\mu$ P-Compatible 5 $\mu$ s, 8-Bit ADCs

conversion, the device ignores the clock input and disables its internal clock signal. Therefore, the external clock may continue to run between conversions without being disabled. The duty cycle ratio of the external clock

may vary from 70/30 to 30/70. As discussed previously, in order to maintain accuracy, clock rates significantly lower than the data sheet limits (4MHz) should not be used.

### Applications Information

#### Unipolar Operation

Figures 16a and 16b show the analog circuit connections and nominal transfer characteristics (Figure 16c) for unipolar operation. Since the offset and full-scale errors of the MAX165/MAX166 are very small, it is not necessary to null these errors in most cases. If calibration is required, make adjustments as follows:

MAX165/MAX166

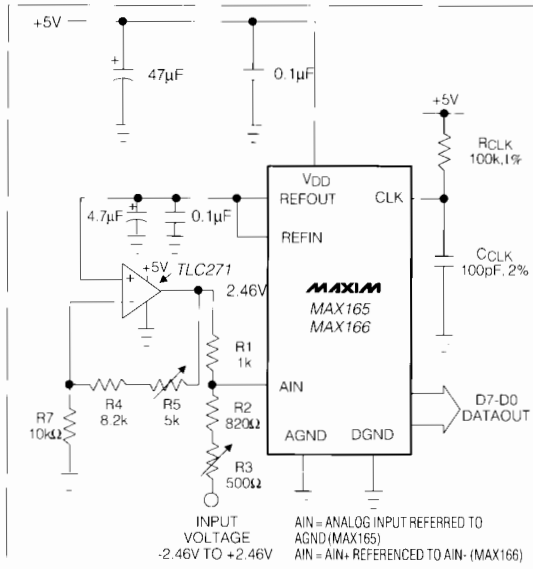

Figure 18a. MAX165/MAX166 Bipolar Configuration (Internal Reference)

Figure 18b. Nominal Transfer Characteristic for Bipolar Operation

### Offset Adjustment

The offset error can be easily adjusted using an op amp, as shown in Figure 18a. The op amp should have a common-mode input range that includes 0V. The op amp input is initially set to +4.8mV (+1/2LSB), while its offset is varied until the ADC output code flickers between 0000 0000 and 0000 0001.

### Full-Scale Adjustment

The full-scale adjustment is made by forcing the analog input, AIN, to +2.445V (FS - 3/2LSB). The reference input voltage is then varied until the ADC output code flickers between 1111 1110 and 1111 1111.

### Bipolar Operation

Figure 18a shows an example of the circuit connections for bipolar operation and its nominal transfer characteristics (Figure 18B). The output code provided by the MAX165/MAX166 is offset binary. The analog input range for this circuit is  $\pm 2.46$ V (1LSB = 19.22mV), even though the voltage appearing at the AIN pin is in the 0V to +2.46V range. In most cases, the MAX165/MAX166's accuracy is high enough that calibration will not be necessary. If calibration is not needed, resistors R1 through R7 should have a 0.1% tolerance, with R4 and R5 replaced by one 10k $\Omega$  resistor, and R2 and R3 with one 1k $\Omega$  resistor. If calibration is required, make adjustments as follows:

### Offset Adjustment

Adjust the offset error by applying an analog input voltage of +2.43V (+FS - 3/2LSB). Resistor R5 is then adjusted until the output code flickers between 1111 1110 and 1111 1111.

### Full-Scale Adjustment

The full-scale errors are nulled by applying an analog input voltage of -2.45V (-FS + 1/2LSB). Resistor R3 is then adjusted until the output code flickers between 0000 0000 and 0000 0001.

### Noise

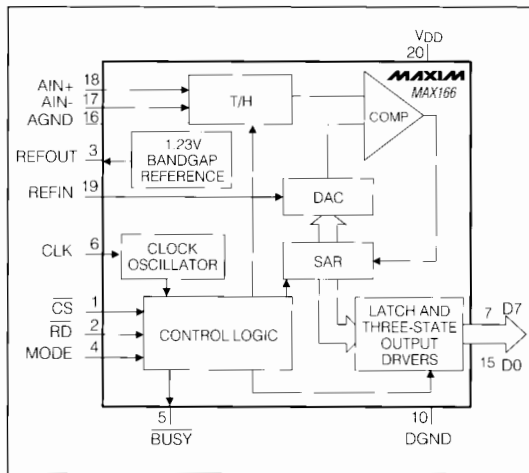

To minimize noise coupling, keep both the input signal lead to AIN and the signal return lead from AGND as short as possible. If this is not possible, a shielded cable or a twisted pair transmission line is recommended. Additionally, potential differences between the ADC ground and the signal source ground should be minimized since these voltage differences appear as errors superimposed on the input signal. In order to minimize system noise pickup, the driving source resistance should be kept below 2k $\Omega$ .

## Proper Layout

For PC board layouts, take care to keep digital lines well separated from any analog lines. A single-point, analog ground, which is separate from the digital system ground, should be established near the MAX165/MAX166. Connect this analog ground point to the digital system ground through a single-track connection only. Any supply or reference bypass capacitors, analog input filter capacitors, or input signal shielding should be returned to the analog ground point.
