

### FEATURES

#### AD363

**16-Channel Data Acquisition Input Stage with:**  
**Digitally Controlled Channel Selection/Mode Control**  
**16 Single-Ended or 8 Differential Channels**  
**25 kHz Throughput Rate**  
**Guaranteed No Missing Codes Over Temperature**

#### AD364

**16-Channel Data Acquisition Input Stage with:**  
**Digitally Controlled Channel Selection/Mode Control**  
**16 Single-Ended or 8 Differential Channels**  
**20 kHz Throughput Rate**  
**Guaranteed No Missing Codes Over Temperature**  
**Three-State Buffered Digital Output**

### PRODUCT DESCRIPTIONS

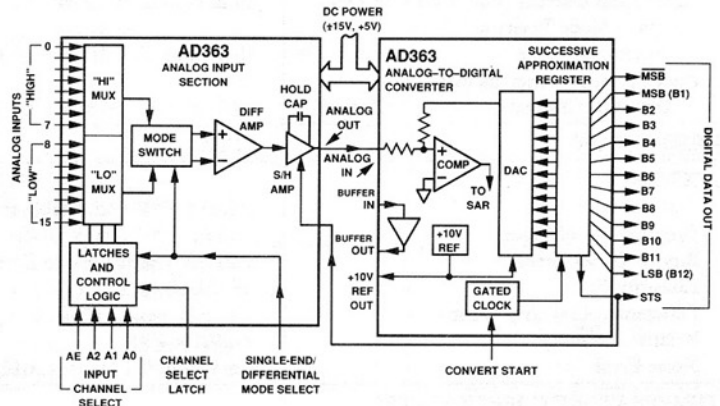

The AD363 and AD364 are complete 16-channel data acquisition systems which condition and subsequently convert an analog voltage into digital form. Each system consists of two devices, an analog input stage (AIS) and an analog-to-digital converter (ADC). The AIS includes a two 8-channel multiplexers, a channel address register, a unity gain instrumentation amplifier, and a sample-hold amplifier. The multiplexers may be connected to the instrumentation amplifier in either an 8-channel differential or 16-channel single ended configuration. A unique feature of these products is an internal user controlled switch which connects the multiplexers in either single-ended or differential mode. This allows a single device to perform in either mode with hard-wire programming and permits interfacing a mixture of single-ended and differential signals by dynamically switching the input mode control.

The AD363 and AD364 differ in ADC performance. Each ADC is a complete 12-bit successive approximation converter including an internal clock and a precision reference. Active laser trimming results in maximum linearity errors of  $\pm 0.012\%$  with conversion times of 25  $\mu\text{s}$  (AD363) or 32  $\mu\text{s}$  (AD364). The hybrid AD363-ADC has five user selectable input ranges ( $\pm 2.5$ ,  $\pm 5.0$ ,  $\pm 10.0$ , 0 to +5, and 0 to +10 volts) and includes a high impedance buffer amplifier. The AD364-ADC is a monolithic converter with 3-state output buffer circuitry for direct interface to an 8-, 12-, or 16-bit processor bus and three user selected input ranges ( $\pm 5$ ,  $\pm 10$ , and 0 to +10 volts).

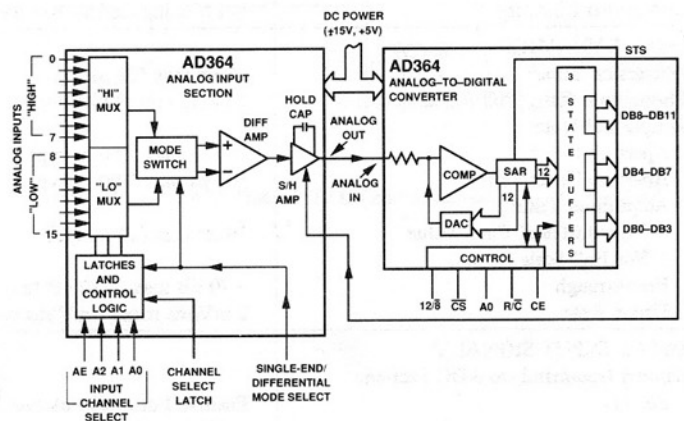

Both products are specified for operation over both the commercial ( $0^\circ\text{C}$  to  $+70^\circ\text{C}$ ) and military ( $-55^\circ\text{C}$  to  $+125^\circ\text{C}$ ) temperature ranges. The AD363 and AD364 are available with environmental screening. Please contact the factory or nearest sales office for details.

# AD363/AD364

AIS Functional Block Diagram

## DESIGN

### Concept

Figures 1 and 2 show a general DAS application using the AD363 and AD364, respectively.

By dividing the data acquisition task into two sections, several important advantages are realized. Performance of each design is optimized for its specific function. Production yields are increased thus decreasing costs. Furthermore, the standard configuration packages plug into standard sockets and are easier to handle than larger packages with higher pin counts.

Figure 1. AD363 DAS

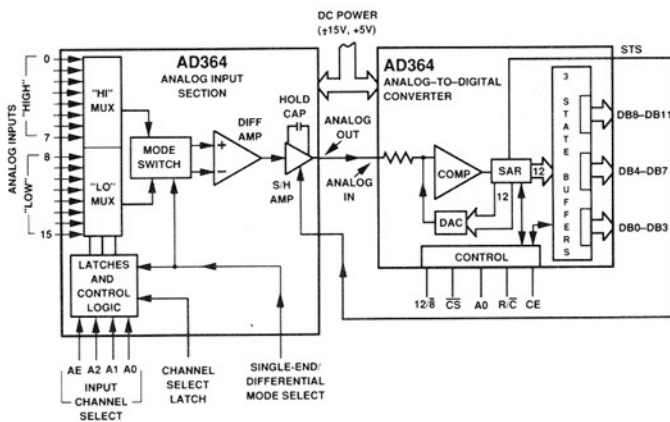

Figure 2. AD364 DAS

## System Timing

Figure 3 is a general timing diagram for the circuits shown in Figures 1 and 2 operating at the maximum conversion rate.

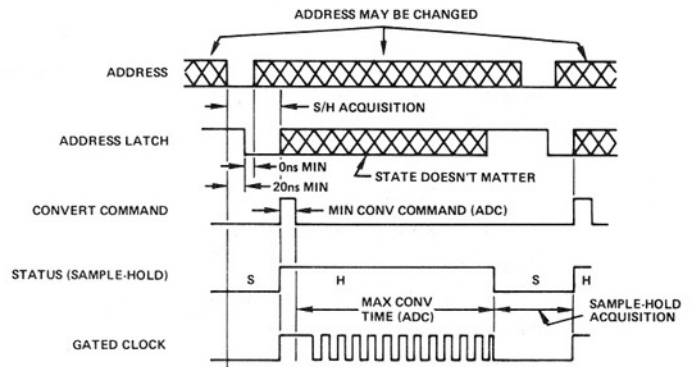

Figure 3. AD363 Timing Diagram

The normal sequence of events is as follows:

1. The appropriate Channel Select Address is latched into the address register. Time is allowed for the multiplexers to settle.
2. A Convert Start command is issued to the ADC which, in response, indicates that it is "busy" by placing a Logic "1" on its Status line.
3. The ADC Status controls the sample-and-hold. When the ADC is "busy," the sample-and-hold is the Hold mode.
4. The ADC goes into its conversion routine. Since the sample-and-hold is holding the proper analog value, the address may be updated during conversion. Thus multiplexer settling time can coincide with conversion and need not affect throughput rate.
5. The ADC indicates completion of its conversion by returning Status to Logic "0." The sample-and-hold returns to the Sample mode.
6. If the input signal has changed full scale (different channels may be widely varying data) the sample-and-hold will typically require 10 microseconds to "acquire" the next input to sufficient accuracy for 12-bit conversion.

After allowing a suitable interval for sample-and-hold to stabilize at its new value, another Convert Start command may be issued to the ADC.

## AD363-ADC OPERATION

Figure 4 shows a detailed timing diagram for the AD363-ADC. Serial data changes on rising edges of the internal clock and is guaranteed to be stable on falling edges.

## AD364-ADC OPERATION

There are two sets of control pins on the AD364-ADC: the general control inputs (CE, CS, and R/C) and the internal register controls inputs (12/8 and A<sub>0</sub>). The general control pins function similarly to those on most A/D converters, performing device timing, addressing, cycle initiation, and read enable functions. The internal register control inputs, which are not found on most A/D converters, select output data format and conversion cycle length.

Figure 4. AD363-ADC Timing Diagram (Binary Code 110101011001)

The two major control functions, convert start and read enable, are controlled by CE,  $\overline{CS}$ , and  $\overline{R/C}$ . Although all three inputs must be in the correct state to perform the function (for convert start, CE = 1,  $\overline{CS}$  = 0,  $\overline{R/C}$  = 0; for read enable, CE = 1,  $\overline{CS}$  = 0,  $\overline{R/C}$  = 1), the sequence does not matter. For large systems, typically microprocessor controlled, standard operation for convert start would be to first set  $\overline{R/C}$  = 0 (from  $\overline{R/W}$  line); address the chip with  $\overline{CS}$  = 0, then apply a positive start pulse to CE. A read would be done similarly but with  $\overline{R/C}$  = 1.

$A_0$  (byte select) and  $12/\overline{8}$  (data format) inputs work together to control the output data and conversion cycle. In almost all situations  $12/\overline{8}$  is hard-wired "high" (to  $V_{LOGIC}$ ) or "low" (to Digital Common). If it is wired high, all 12 data lines will be enabled when the read function is called by the general control inputs. For an 8-bit bus interface,  $12/\overline{8}$  will be wired low. In this mode, only the 8 upper bits or the 4 lower bits can be enabled at once, as addressed by  $A_0$ . For these applications, the 4 LSBs (Pins 16–19) should be hard-wired to the 4 MSBs (Pins 24–27). Thus, during a read, when  $A_0$  is low, the upper 8 bits are enabled and present data on Pins 20 through 27. When  $A_0$  goes high, the upper 8 data bits are disabled, the 4 LSBs then present data to Pins 24 to 27, and the 4 middle bits are overridden so that zeros are presented to Pins 20 through 23.

The  $A_0$  input performs an additional function of controlling conversion length. If  $A_0$  is held low prior to cycle initiation, a full 12-bit, 25  $\mu$ s cycle will result; if  $A_0$  is held high prior to cycle initiation, a shortened 8-bit, 16  $\mu$ s cycle will result. The  $A_0$  line must be set prior to cycle initiation and held in the desired position at least until STS goes high. Thus, for micro-

processor interface applications, the  $A_0$  line must be properly controlled during both the convert start and read functions.

### STANDARD FULL CONTROL INTERFACE

The timing for the standard full control interface is shown in Figure 5. In this operating mode,  $\overline{CS}$  is used as the address input which selects the particular device,  $\overline{R/C}$  selects between the read data and start conversion functions, and CE is used to time the actual functions.

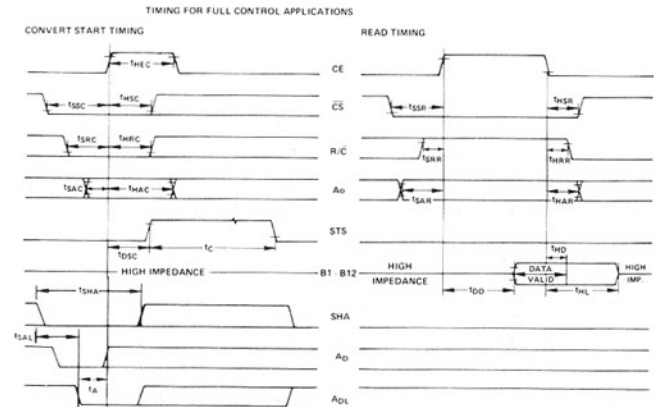

Figure 5. AD364-ADC Timing Diagram

The left side of the figure shows the conversion start control.  $\overline{CS}$  and  $\overline{R/C}$  are brought low (their sequence does not matter), then the start pulse is applied to CE. The timing diagram shows a time delay for  $\overline{CS}$  and  $\overline{R/C}$  prior to the start pulse at CE. If less time than this is allowed, the conversion will still be started, but an appropriately longer pulse will be needed at CE. However, if the hold times for  $\overline{CS}$  and  $\overline{R/C}$  after the rising edge of the start pulse at CE are not followed, the conversion may not be initiated.

The  $A_0$  line determines the conversion cycle length and must be selected prior to conversion initiation. If  $A_0$  is low, a 12-bit cycle results; if  $A_0$  is high, an 8-bit short cycle results. Minimum setup and hold times are shown. The status line goes high to indicate conversion in progress. The analog input signal is allowed to vary until the STS goes high. It must then be held steady until STS again goes low at the end of conversion.

The data read function operates in a similar fashion except that  $\overline{R/C}$  is now held high. The data is stored in the output register and can be recalled at will until a new conversion cycle is commanded. In addition, if the converter is arranged in the 8-bit data mode, the  $A_0$  line now functions as the byte select address, with setup and hold times as shown. With  $A_0$  low, Pins 20 to 27 (DB4–11) come out of three-state and present data. With  $A_0$  high, Pins 16–19 (DB0–3) come out of three-state with data and Pins 20–23 present active trailing zeros. In the 8-bit mode, Pins 16–19 will be hard-wired directly to Pin 24–27 for direct two byte loading onto an 8-bit bus. There are two delay times for the data lines after CE is brought low:  $t_{HD}$  is the delay until the outputs are fully into the high impedance state.

### STANDALONE OPERATION

For simpler control functions, the AD364-ADC can be controlled with just  $\overline{R/C}$ . In this case, CE is wired high,  $\overline{CS}$  low,  $12/\overline{8}$  high, and  $A_0$  low. There are two ways of cycling the device

## TIMING SPECIFICATIONS—FULL CONTROL MODE

$t_{DSC}$	400 ns max	$t_{DD}$	200 ns max
$t_{HEC}$	300 ns min	$t_{HD}$	25 ns min
$t_{SSC}$	300 ns min	$t_{SSR}$	150 ns min
$t_{HSC}$	200 ns min	$t_{SRR}$	0 min
$t_{SRC}$	250 ns min	$t_{SAR}$	150 ns min
$t_{HRC}$	200 ns min	$t_{HSR}$	50 ns min
$t_{SAC}$	0 min	$t_{HRR}$	0 min
$t_{HAC}$	300 ns min	$t_{HAR}$	50 ns min
$t_C$	15–35 $\mu$ s (12-Bit)	$t_{HL}$	150 ns max
	10–24 $\mu$ s (8-Bit)	$t_{SAL}$	20 ns min
$t_{SHA}$	10–18 $\mu$ s	$t_{SA}$	0 min

with this simple hookup. If a negative pulse is used to initiate conversion as in Figure 6, the converter will automatically bring the 12 data lines out of three-state at the end of conversion. The data will remain valid on the output lines until another pulse is applied.

If the conversion is initiated by a high pulse as shown in Figure 7, the data lines are held in three-state at the end of conversion until  $R/\bar{C}$  is brought high. The next conversion cycle is initiated when  $R/\bar{C}$  goes low; the data from the previous cycle will remain valid for the time  $t_{HDR}$ . An alternative to the above is to toggle  $R/\bar{C}$  as needed to initiate a new cycle on read data. Data will appear when  $R/\bar{C}$  is brought high, a new cycle is initiated when  $R/\bar{C}$  goes low.

## APPLICATIONS

### Single-Ended/Differential Mode Control

The AIS features an internal analog switch that configures the Analog Input Section in either a 16-channel single-ended or 8-channel differential mode. This switch is controlled by a non-TTL logic input applied to Pin 1 of the Analog Input Section:

“0”: Single-Ended (16 Channels)

“1”: Differential (8 Channels) (+4.0 V min)

When in the differential mode, a differential source may be applied between corresponding “High” and “Low” analog input channels.

It is possible to mix SE and DIFF inputs by using the mode control to command the appropriate mode. In this case, four microseconds must be allowed for the output of the Analog Input Section to settle to within  $\pm 0.01\%$  of its final value, but if the mode is switched concurrent with changing the channel address, no significant additional delay is introduced. The effect of this delay may be eliminated by changing modes while a conversion is in progress (with the sample-and-hold in the “Hold” mode). When SE and DIFF signals are being processed concurrently, the DIFF signals must be applied between corresponding “High” and “Low” analog input channels. Another application of this feature is the capability of measuring 16 sources individually and/or measuring differences between pairs of those sources.

### Input Channel Addressing

Table I is the truth table for input channel addressing in both the single-ended and differential modes. The 16-single-ended channels may be addressed by applying the corresponding digital number to the four Input Channel Select address bits, AE, A0, A1, A2 (Pins 28–31). In the differential mode, the eight channels are addressed by applying the appropriate digital code to A0, A1, and A2; AE must be enabled with a Logic “1.” Internal logic monitors the status of the SE/DIFF Mode input and addresses the multiplexers singularly or in pairs as required.

ADDRESS				ON CHANNEL (Pin Number)	
AE	A2	A1	A0	Single-Ended	Differential “Hi” “Lo”
0	0	0	0	0 (11)	None
0	0	0	1	1 (10)	None
0	0	1	0	2 (9)	None
0	0	1	1	3 (8)	None
0	1	0	0	4 (7)	None
0	1	0	1	5 (6)	None
0	1	1	0	6 (5)	None
0	1	1	1	7 (4)	None
1	0	0	0	8 (27)	0 (11) 0 (27)
1	0	0	1	9 (26)	1 (10) 1 (26)
1	0	1	0	10 (25)	2 (9) 2 (25)
1	0	1	1	11 (24)	3 (8) 3 (24)
1	1	0	0	12 (23)	4 (7) 5 (23)
1	1	0	1	13 (22)	5 (6) 5 (22)
1	1	1	0	14 (19)	6 (5) 6 (19)
1	1	1	1	15 (18)	7 (4) 7 (18)

Table I. Input Channel Addressing Truth Table

When the channel address is changed, six microseconds must be allowed for the Analog Input Section to settle to within  $\pm 0.01\%$  of its final output (including settling times of all elements in the signal path). The effect of this delay may be eliminated by performing the address change while a conversion is in progress (with the sample-and-hold in the “hold” mode). All unused inputs must be grounded.

#### Input Channel Address Latch

The AIS is equipped with a latch for the Input Channel Select address bits. If the Latch Control pin (Pin 32) is at Logic “1,” input channel select address information is passed through to the multiplexers. A Logic “0” “freezes” the input channel address present at the inputs at the “1”-to-“0” transition level-triggered.

This feature is useful when input channel address information is provided from an address, data or control bus that may be required to service many devices. The ability to latch an address is helpful whenever the user has no control of when address information may change.

#### Sample-and-Hold Mode Control

The Sample-and-Hold Mode Control input (Pin 13) is normally connected to the Status output (Pin 20) from an analog-to-digital converter. When a conversion is initiated by applying a Convert Start command to the ADC, Status goes to Logic “1,” putting the sample-and-hold in to the “Hold” mode. This “freezes” the information to be digitized for the period of conversion. When the conversion is complete, Status returns to Logic “0” and the sample-and-hold returns to the “Sample” mode. Eighteen microseconds must be allowed for the sample-and-hold to acquire (“catch up” to) the analog input to within  $\pm 0.01\%$  of the final value before a new Convert Start command is issued.

The purpose of a sample-and-hold is to “stop” fast changing input signals long enough to be converted. In this application, it also allows the user to change channels and/or SE/DIFF mode while a conversion is in progress thus eliminating the effects of multiplexer, analog switch and differential amplifier settling times. If maximum throughput rate is required for slowly changing signals, the Sample-and-Hold Mode Control may be wired to ground (Logic “0”) rather than to ADC Status thus leaving the sample-and-hold in a continuous sample mode.

#### Analog Input Section Offset Adjust Circuit

Although the offset voltage of the AIS may be adjusted, that adjustment is normally performed at the ADC. In some special applications, however, it may be helpful to adjust the offset of the Analog Input Section. An example of such a case would be if the input signals were small ( $< 10$  mV) relative to the AIS voltage offset and if a gain stage was to be inserted between the AIS and the ADC. To adjust the offset of the AIS, the circuit shown in Figure 8 is recommended.

Figure 8. AIS Offset Voltage Adjustment

Under normal conditions, all calibration is performed at the ADC Section.

**Gain Adjust, AD363-ADC:** Gain may be adjusted by connecting a  $100\ \Omega$  potentiometer between +10 V Reference Output and Gain Adjust Input (ADC Pins 18 and 27). A multi-turn, low temperature coefficient potentiometer, such as a 20-turn cermet device, is recommended. This potentiometer may be replaced with a  $50\ \Omega$ , 0.1% resistor to obtain an absolute gain calibration of 0.05% without trimming.

**Offset Adjust, AD363-ADC:** The simplest offset adjust circuit requires a 20-turn, 20 k $\Omega$  cermet potentiometer and a 3.9 M $\Omega$  resistor as shown in Figure 9a. This arrangement has an adjustment range of  $\pm 8$  LSBs, and will contribute a maximum of 2.3 ppm/ $^{\circ}\text{C}$  offset drift with a carbon composition fixed resistor ( $\text{TC} = -1200$  ppm/ $^{\circ}\text{C}$ ). Drift contributions from the offset adjust circuit can be reduced well below this level using metal-film resistors and the circuit of Figure 9b.

**Gain Adjust, AD364-ADC:** Gain may be adjusted by connecting a  $100\ \Omega$  potentiometer between the Reference Output and Reference Input (ADC Pins 8 and 10). A multi-turn, low temperature coefficient potentiometer, such as a 20T cermet device, is recommended. A fixed  $50\ \Omega$ , 1% resistor should be connected between Pins 8 and 10 if no gain trim is required.

Figure 9a.

Figure 9b.

**Offset Adjust, AD364-ADC:** Offset adjust circuits for unipolar and bipolar operation are shown in Figures 10a and 10b. In each case the potentiometer should be a multi-turn, low temperature coefficient device, such as 20-turn cermet. Lowest offset drift in unipolar operation will be realized when the fixed resistors are low-TC (100 ppm/ $^{\circ}\text{C}$ ) metal-film types.

# AD363/AD364

If no offset adjustment is desired, Pin 12 should be connected to Pin 9 (unipolar mode) or to Pin 8 through a 50 Ω 1% resistor (bipolar mode).

Figure 10a. Unipolar Gain & Offset

Figure 10b. Bipolar Gain & Offset

**Input Scaling:** Connections for the various ADC input ranges are given in Tables II and III.

**Buffer:** An uncommitted unity-gain buffer is available in the AD363-ADC. This buffer has a 2 μs settling time to 0.01% for a 20 V step. Its input should be grounded if the buffer is not used.

Range	Connect Analog Input To Pin:	Connect Span Pin:	Connect Bipolar Pin 23 To:
0 to +5 V	24	25 to 22	22
0 to +10 V	24	—	
-2.5 V to +2.5 V	24	25 to 22	
-5 V to +5 V	24	—	
-10 V to +10 V	25	—

## Other Considerations

**Grounding:** Analog and digital signal grounds should be kept separate where possible to prevent digital signals from flowing in the analog ground circuit and inducing spurious analog signal noise. Analog Ground (Pin 17) and Digital Ground (Pin 2) are not connected internally; these pins must be connected externally for the system to operate properly. Preferably, this connection is made at only one point, as close to the AIS, as possible. The case is connected internally to Digital Ground to provide good electrostatic shielding. If the grounds are not tied common on the same card with the AIS they should be connected with back-to-back general purpose diodes as shown in Figure 11. This will protect the AIS from possible damage caused by voltages in excess of ±1 volt between the ground systems which could occur if the key grounding card should be removed from the overall system. The device will operate properly with as much as ±200 mV between grounds, however this difference will be reflected directly as an input offset voltage.

Figure 11. Ground-Fault Protection Diodes

**Power Supply Bypassing:** The ±15 V and +5 V power leads should be capacitively bypassed to Analog Ground and Digital Ground respectively for optimum device performance. 1 μF tantalum types are recommended; these capacitors should be located close to the system. It is not necessary to shunt these capacitors with disc capacitors to provide additional high frequency power supply decoupling since each power lead is bypassed internally with a 0.039 μF ceramic capacitor.
