

# LC<sup>2</sup>MOS High Speed $\mu$ P-Compatible 8-Bit ADC with Track/Hold Function

## AD7820

### FEATURES

- Fast Conversion Time: 1.36 $\mu$ s max
- Built-In Track-and-Hold Function
- No Missed Codes
- No User Trims Required
- Single +5V Supply
- Ratiometric Operation
- No External Clock
- Extended Temperature Range Operation
- Skinny 20-Pin DIP, SOIC and 20-Terminal Surface Mount Packages

### GENERAL DESCRIPTION

The AD7820 is a high speed, microprocessor-compatible 8-bit analog-to-digital converter which uses a half-flash conversion technique to achieve a conversion time of 1.36 $\mu$ s. The converter has a 0V to +5V analog input voltage range with a single +5V supply.

The half-flash technique consists of 31 comparators, a most significant 4-bit ADC and a least significant 4-bit ADC. The input to the AD7820 is tracked and held by the input sampling circuitry, eliminating the need for an external sample-and-hold for signals with slew rates less than 100mV/ $\mu$ s.

The part is designed for ease of microprocessor interface with the AD7820 appearing as a memory location or I/O port without the need for external interfacing logic. All digital outputs use latched, three-state output buffer circuitry to allow direct connection to a microprocessor data bus or system input port. A non-three state overflow output is also provided to allow cascading of devices to give higher resolution.

The AD7820 is fabricated in an advanced, all ion-implanted, high speed, Linear Compatible CMOS (LC<sup>2</sup>MOS) process and features a low maximum power dissipation of 75mW. It is available in 20-pin DIPs, SOICs and in 20-terminal surface mount packages.

### REV. A

Information furnished by Analog Devices is believed to be accurate and reliable. However, no responsibility is assumed by Analog Devices for its use; nor for any infringements of patents or other rights of third parties which may result from its use. No license is granted by implication or otherwise under any patent or patent rights of Analog Devices.

### FUNCTIONAL BLOCK DIAGRAM

### PRODUCT HIGHLIGHTS

- Fast Conversion Time**  
The half-flash conversion technique, coupled with fabrication on Analog Devices' LC<sup>2</sup>MOS process, enables very fast conversion times. The maximum conversion time for the WR-RD mode is 1.36 $\mu$ s, with 1.6 $\mu$ s the maximum for the RD mode.
- Total Unadjusted Error**  
The AD7820 features an excellent total unadjusted error figure of less than 1/2LSB over the full operating temperature range. The part is also guaranteed to have no missing codes over the entire temperature range.
- Built-In Track-and-Hold**  
The analog input circuitry uses sampled-data comparators, which by nature have a built-in track-and-hold function. As a result, input signals with slew rates up to 100mV/ $\mu$ s can be converted to 8-bits without external sample-and-hold. This corresponds to a 5V peak-to-peak, 7kHz sine-wave signal.
- Single Supply**  
Operation from a single +5V supply with a positive voltage reference allows operation of the AD7820 in microprocessor systems without any additional power supplies.

Derates above +75°C by	6mW/°C

\*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## CAUTION:

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

## PIN FUNCTION DESCRIPTION

PIN	MNEMONIC	DESCRIPTION
1	$V_{IN}$	Analog Input. Range: $V_{REF(-)}$ to $V_{REF(+)}$ .
2	DB0	Data Output. Three State Output, bit 0 (LSB)
3	DB1	Data Output. Three State Output, bit 1
4	DB2	Data Output. Three State Output, bit 2
5	DB3	Data Output. Three State Output, bit 3
6	$\overline{WR/RDY}$	WRITE control input/READY status output. See Digital Interface section.
7	Mode	Mode Selection Input. It determines whether the device operates in the $\overline{WR}$ -RD or RD mode. It is internally tied to GND through a $50\mu A$ current source. See Digital Interface section.
8	$\overline{RD}$	READ Input. $\overline{RD}$ must be low to access data from the part. See Digital Interface section.
9	$\overline{INT}$	INTERRUPT Output. $\overline{INT}$ going low indicates that the conversion is complete. $\overline{INT}$ returns high on the rising edge of $\overline{RD}$ or $\overline{CS}$ . See Digital Interface section.
10	GND	Ground
11	$V_{REF(-)}$	Lower limit of reference span. Range: $GND \leq V_{REF(-)} \leq V_{REF(+)}$
12	$V_{REF(+)}$	Upper limit of reference span. Range: $V_{REF(-)} \leq V_{REF(+)} \leq V_{DD}$
13	$\overline{CS}$	Chip Select Input. $\overline{CS}$ , the decoded device address, must be low for RD or $\overline{WR}$ to be recognized by the converter.
14	DB4	Data Output. Three State Output, bit 4
15	DB5	Data Output. Three State Output, bit 5
16	DB6	Data Output. Three State Output, bit 6
17	DB7	Data Output. Three State Output, bit 7 (MSB)
18	$\overline{OFL}$	Overflow Output. If the analog input is higher than $(V_{REF(+)} - 1/2LSB)$ , $\overline{OFL}$ will be low at the end of conversion. It is a non three state output which can be used to cascade 2 or more devices to increase resolution.
19	NC	No connection.
20	$V_{DD}$	Power supply voltage, +5V

## CIRCUIT INFORMATION

### BASIC DESCRIPTION

The AD7820 uses a half-flash conversion technique whereby two 4-bit flash A/D converters are used to achieve an 8-bit result. Each 4-bit flash ADC contains 15 comparators which compare the unknown input to a reference ladder to get a 4-bit result. For a full 8-bit reading to be realized, the upper 4-bit flash, the most significant (MS) flash, performs a conversion to provide the 4 most significant data bits. An internal DAC, driven by the 4 MSBs, then recreates an analog approximation of the input voltage. This analog result is subtracted from the input, and the difference is converted by the lower flash ADC, the least significant (LS) flash, to provide the 4 least significant bits of the output data. The MS flash ADC also has one additional comparator to detect input overrange.

### OPERATING SEQUENCE

The operating sequence for the AD7820 in the  $\overline{WR}$ -RD mode is shown in Figure 3. A set-up time of 500ns is required prior to the falling edge of  $\overline{WR}$ . (This 500ns is required between reading data from the AD7820 and starting another conversion). When  $\overline{WR}$  is low the input comparators track the analog input signal,  $V_{IN}$ . On the rising edge of  $\overline{WR}$ , the input signal is sampled and the result for the four most significant bits is latched.  $\overline{INT}$  goes low approximately 700ns after the rising edge of  $\overline{WR}$ . This indicates that conversion is complete and the data result is already in the output latch.  $\overline{RD}$  going low then accesses the output data. If a faster conversion time is required, the  $\overline{RD}$  line can be brought low 600ns after  $\overline{WR}$  goes high. This latches the lower 4 bits of data and accesses the output data on DB0-DB7.

Figure 3. Operating Sequence ( $\overline{WR}$ -RD Mode)

**DIGITAL INTERFACE**

The AD7820 has two basic interface modes which are determined by the status of the MODE pin. When this pin is low the converter is in the RD mode, with this pin high the AD7820 is set up for the WR-RD mode.

**RD Mode**

The timing diagram for the RD mode is shown in Figure 4. In the RD mode configuration, conversion is initiated by taking RD low. The RD line is then kept low until output data appears. It is very useful with microprocessors which can be forced into a WAIT state, with the microprocessor starting a conversion, waiting, and then reading data with a single READ instruction. In this mode, pin 6 of the AD7820 is configured as a status output, RDY. This RDY output can be used to drive the processor READY or WAIT input. It is an open drain output (no internal pull-up device) which goes low after the falling edge of CS and goes high impedance at the end of conversion. An INT line is also provided which goes low at the completion of conversion. INT returns high on the rising edge of CS or RD.

Figure 4. RD Mode

**WR-RD Mode**

In the WR-RD mode, pin 6 is configured as the WRITE input for the AD7820. With CS low, conversion is initiated on the falling edge of WR. Two options exist for reading data from the converter.

Figure 5a. WR-RD Mode (t<sub>RD</sub> > t<sub>INTL</sub>)

In the first of these options the processor waits for the INT status line to go low before reading the data (see Figure 5a). INT typically goes low 700ns after the rising edge of WR. It indicates that conversion is complete and that the data result is in the output latch. With CS low, the data outputs (DB0-DB7) are activated when RD goes low. INT is reset by the rising edge of RD or CS.

The alternative option can be used to shorten the conversion time. To achieve this, the status of the INT line is ignored and RD can be brought low 600ns after the rising edge of WR. In this case RD going low transfers the data result into the output latch and activates the data outputs (DB0-DB7). INT also goes low on the falling edge of RD and is reset on the rising edge of RD or CS. The timing for this interface is shown in Figure 5b.

Figure 5b. WR-RD Mode (t<sub>RD</sub> < t<sub>INTL</sub>)

The AD7820 can also be used in stand-alone operation in the WR-RD mode. CS and RD are tied low and a conversion is initiated by bringing WR low. Output data is valid typically 700ns after the rising edge of WR. The timing diagram for this mode is shown in Figure 6.

Figure 6. WR-RD Mode Stand-Alone Operation, CS = RD = 0

# AD7820

## APPLYING THE AD7820 REFERENCE AND INPUT

The two reference inputs on the AD7820 are fully differential and define the zero to full-scale input range of the A/D converter. As a result, the span of the analog input can easily be varied since this range is equivalent to the voltage difference between  $V_{IN}(+)$  and  $V_{IN}(-)$ . By reducing the reference span,  $V_{REF}(+) - V_{REF}(-)$ , to less than 5V the sensitivity of the converter can be increased (i.e., if  $V_{REF} = 2V$  then  $1LSB = 7.8mV$ ). The input/reference arrangement also facilitates ratiometric operation.

This reference flexibility also allows the input span to be offset from zero. The voltage at  $V_{REF}(-)$  sets the input level which produces a digital output of all zeroes. Therefore, although  $V_{IN}$  is not itself differential, it will have nearly differential-input capability in most measurement applications because of the reference design. Figure 7 shows some of the configurations that are possible.

### INPUT CURRENT

Due to the novel conversion techniques employed by the AD7820, the analog input behaves somewhat differently than in conventional devices. The ADC's sampled-data comparators take varying amounts of input current depending on which cycle the conversion is in.

The equivalent input circuit of the AD7820 is shown in Figure 8a. When a conversion starts ( $\overline{WR}$  low,  $WR-RD$  mode), all input switches close, and  $V_{IN}$  is connected to the most significant and least significant comparators. Therefore,  $V_{IN}$  is connected to thirty one  $1pF$  input capacitors at the same time.

The input capacitors must charge to the input voltage through the on resistance of the analog switches (about  $2k\Omega$  to  $5k\Omega$ ). In addition, about  $12pF$  of input stray capacitance must be charged. For large source resistances, the analog input can be modelled as an RC network as shown in Figure 8b. As  $R_S$  increases, it takes longer for the input capacitance to charge.

In the RD mode, the time for which the input comparators track the analog input is  $600ns$  at the start of conversion. In the  $WR-RD$  mode the input comparators track  $V_{IN}$  for the duration of the  $\overline{WR}$  pulse. Since other factors cause this time to be at least  $600ns$ , input time constants of  $100ns$  can be accommodated without special consideration. Typical total input capacitance values of  $45pF$  allow  $R_S$  to be  $1.5k\Omega$  without lengthening  $\overline{WR}$  to give  $V_{IN}$  more time to settle.

Figure 8b. RC Network Model

**INPUT FILTERING**

It should be made clear that transients on the analog input signal, caused by charging current flowing into  $V_{IN}$  will normally degrade the ADC's performance. In effect, the AD7820 does not "look" at the input when these transients occur. The

comparators' outputs are not latched while  $\overline{WR}$  is low, so at least 600ns will be provided to charge the ADC's input capacitance. It is therefore not necessary to filter out these transients with an external capacitor at the  $V_{IN}$  terminal.

**INHERENT SAMPLE-HOLD**

A major benefit of the AD7820's input structure is its ability to measure a variety of high speed signals without the help of an external sample-and-hold. In a conventional SAR type converter, regardless of its speed, the input must remain stable to at least  $\frac{1}{2}$ LSB throughout the conversion process if full accuracy is to be maintained. Consequently, for many high speed signals, this signal must be externally sampled and held stationary during the conversion. The AD7820 input comparators, by nature of their input switching inherently accomplish this sample-and-hold function. Although the conversion time for the AD7820 is 1.36 $\mu$ s, the time through which  $V_{IN}$  must be  $\frac{1}{2}$ LSB stable is much smaller. The AD7820 "samples"  $V_{IN}$  only when  $\overline{WR}$  is low. The value of  $V_{IN}$  approximately 100ns (internal propagation delay) after the rising edge of  $\overline{WR}$  is the measured value. This value is then used in the least significant flash to generate the lower 4-bits of data.

Input signals with slew rates typically below 200mV/ $\mu$ s can be converted without error. However, because of the input time constants, and charge injection through the opened comparator input switches, faster signals may cause errors. Still, the AD7820's loss in accuracy for a given increase in signal slope is far less than what would be witnessed in a conventional successive approximation device. A SAR type converter with a conversion time as fast as 1 $\mu$ s would still not be able to measure a 5V, 1kHz sine wave without the aid of an external sample-and-hold. The AD7820 with no such help, can typically measure 5V, 10kHz waveforms.
