

FEATURES

- ± 200 g measurement range**
- 200 Hz to 3200 Hz user selectable bandwidth with 4-pole antialiasing filter**
- Selectable oversampling ratio**
- Adjustable high-pass filter**
- Ultralow power**
 - Power can be derived from a coin cell battery**
 - 22 μ A at 3200 Hz ODR, 2.5 V supply**
 - Low power, wake-up mode for low g activity detection**
 - 1.4 μ A instant on mode with adjustable threshold**
 - <0.1 μ A standby mode**
- Built in features for system level power savings**
 - Autonomous interrupt processing without processor intervention**
 - Deep embedded FIFO to minimize host processor load**
- Ultralow power event monitoring detects impacts and wakes up fast enough to capture the transient events**
- Ability to capture and store peak acceleration values of events**
- Adjustable, low g threshold activity and inactivity detection**
- Wide supply range: 1.6 V to 3.5 V**
- Acceleration sample synchronization via external trigger**
- SPI digital interface and limited I²C interface format support**
- 12-bit output at 100 mg/LSB scale factor**
- Wide temperature range: -40°C to $+105^{\circ}\text{C}$**
- Small, thin, 3 mm \times 3.25 mm \times 1.06 mm package**

APPLICATIONS

- Impact and shock detection**
- Asset health assessment**
- Portable Internet of Things (IoT) edge nodes**
- Concussion and head trauma detection**

GENERAL DESCRIPTION

The [ADXL372](#) is an ultralow power, 3-axis, ± 200 g MEMS accelerometer that consumes 22 μ A at a 3200 Hz output data rate (ODR). The [ADXL372](#) does not power cycle its front end to achieve its low power operation and therefore does not run the risk of aliasing the output of the sensor.

In addition to its ultralow power consumption, the [ADXL372](#) has many features to enable impact detection while providing system level power reduction. The device includes a deep multimode output first in, first out (FIFO), several activity detection modes, and a method for capturing only the peak acceleration of over threshold events.

Two additional lower power modes with interrupt driven, wake-up features are available for monitoring motion during periods of inactivity. In wake-up mode, acceleration data can be averaged to obtain a low enough output noise to trigger on low g thresholds. In instant on mode, the [ADXL372](#) consumes 1.4 μ A while continuously monitoring the environment for impacts. When an impact event that exceeds the internally set threshold is detected, the device switches to normal operating mode fast enough to record the event.

High g applications tend to experience acceleration content over a wide range of frequencies. The [ADXL372](#) includes a 4-pole low-pass antialiasing filter to attenuate out of band signals that are common in high g applications. The [ADXL372](#) also incorporates a high-pass filter to eliminate initial and slow changing errors, such as ambient temperature drift.

The [ADXL372](#) provides 12-bit output data at 100 mg/LSB scale factor. The user can access configuration and data registers via the serial peripheral interface (SPI) or limited I²C protocol. The [ADXL372](#) operates over a wide supply voltage range and is available in a 3 mm \times 3.25 mm \times 1.06 mm package.

Multifunction pin names may be referenced by their relevant function only.

³ This parameter has an available corner frequency scale with the ODR setting.

⁴ Bandwidth and ODR are set independent of each other.

ABSOLUTE MAXIMUM RATINGS

Table 2.

Parameter	Rating
Acceleration	
Any Axis, Unpowered	10000 g
Any Axis, Powered	10000 g
V_S	-0.3 V to +3.6 V
$V_{DDI/O}$	-0.3 V to +3.6 V
All Other Pins	-0.3 V to V_S
Output Short-Circuit Duration (Any Pin to Ground)	Indefinite
ESD, Human Body Model (HBM)	2000 V
Temperature Range (Storage)	-50°C to +150°C

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

THERMAL RESISTANCE

Thermal performance is directly linked to printed circuit board (PCB) design and operating environment. Careful attention to PCB thermal design is required.

Table 3.

Package Type ¹	θ_{JA}	θ_{JC}	Unit	Device Weight
CC-16-4	150	85	°C/W	18 mg

¹ Thermal impedance simulated values are based on a JEDEC 2S2P thermal test board with four thermal vias. See JEDEC JESD51.

RECOMMENDED SOLDERING PROFILE

Figure 2 and Table 4 provide details about the recommended soldering profile.

Figure 2. Recommended Soldering Profile

Table 4. Recommended Soldering Profile

Profile Feature	Condition	
	Sn63/Pb37	Pb-Free
Average Ramp Rate (T_L to T_P)	3°C/sec max	3°C/sec max
Preheat		
Minimum Temperature (T_{SMIN})	100°C	150°C
Maximum Temperature (T_{SMAX})	150°C	200°C
Time (T_{SMIN} to T_{SMAX}) (t_S)	60 sec to 120 sec	60 sec to 180 sec
T_{SMAX} to T_L		
Ramp-Up Rate	3°C/sec max	3°C/sec max
Time Maintained Above Liquidous (T_L)		
Liquidous Temperature (T_L)	183°C	217°C
Time (t_L)	60 sec to 150 sec	60 sec to 150 sec
Peak Temperature (T_P)	240 + 0/-5°C	260 + 0/-5°C
Time Within 5°C of Actual Peak Temperature (t_P)	10 sec to 30 sec	20 sec to 40 sec
Ramp-Down Rate	6°C/sec max	6°C/sec max
Time 25°C to Peak Temperature	6 minutes max	8 minutes max

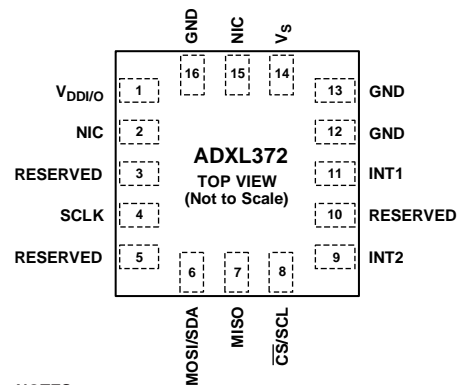

ESD CAUTION

ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

NOTES

THEORY OF OPERATION

The [ADXL372](#) is a complete 3-axis acceleration measurement system that operates at extremely low power levels. Acceleration is reported digitally, and the device communicates via the SPI and I²C protocols. Built in digital logic enables autonomous operation and implements functions that enhance system level power savings.

MECHANICAL DEVICE OPERATION

The moving component of the sensor is a polysilicon surface micromachined structure built on top of a silicon wafer. Polysilicon springs suspend the structure over the surface of the wafer and provide a resistance against acceleration forces.

Deflection of the structure is measured using differential capacitors that consist of independent fixed plates and plates attached to the moving mass. Acceleration deflects the structure and unbalances the differential capacitor, resulting in a sensor output whose amplitude is proportional to acceleration. Phase sensitive demodulation determines the magnitude and polarity of the acceleration.

OPERATING MODES

The [ADXL372](#) has three operating modes: measurement mode for continuous, wide bandwidth sensing; an instant on mode for low power impact detection; and wake-up mode for limited bandwidth low *g* activity detection. Measurement can be suspended by placing the device in standby mode.

Measurement Mode

Measurement mode is the default operating mode of the [ADXL372](#). In this mode, acceleration data is read continuously, and the accelerometer consumes 22 μA (typical) at an ODR of 3200 Hz using a 2.5 V supply. Actual current consumption is dependent on the ODR chosen. All features described in this data sheet are available when operating the [ADXL372](#) in this mode.

Instant On Mode

Instant on mode enables extremely low power impact detection. In this mode, the accelerometer constantly monitors the environment while consuming a very low current of 1.4 μA (typical). When an event that exceeds an internal threshold is detected, the device switches into measurement mode to record the event. The target default threshold is 10 *g* to 15 *g*, but it can vary. A register option allows the threshold to be increased to a target of 30 *g* to 40 *g* if the default threshold is too low.

To save power, no new digital acceleration data is made available until the accelerometer switches into normal operation. However, all registers have normal read/write functionality.

Wake-Up Mode

Wake-up mode is ideal for simple detection of the presence or absence of motion at an extremely low power consumption. Wake-up mode is particularly useful for the implementation of a low *g* motion activated on/off switch, allowing the rest of the system to be powered down until sustained activity is detected.

In wake-up mode, the device is powered down for a duration of time equal to the wake-up timer, set by the WAKEUP_RATE bits in the TIMING register, and then turns on for a duration equal to the filter settling time (see the Filter Settling Time section). The current drawn in this mode is determined by both these parameters.

Table 6. Wake-Up Current in μA at Different Wake-Up Timer and Filter Settings

Wake-Up Timer (ms)	Filter Settling Time	
	16 ms	370 ms
52	5.8 μA	19.4 μA
104	3.6 μA	17.3 μA
208	2.3 μA	14.4 μA
512	1.4 μA	9.7 μA
2048	0.91 μA	4 μA
4096	0.83 μA	2.5 μA
8192	0.79 μA	1.7 μA
24576	0.77 μA	1.1 μA

If motion is detected, the accelerometer can respond autonomously in several ways, depending on the device configuration, such as the following:

- Switch into full bandwidth measurement mode.
- Signal an interrupt to a microcontroller.
- Wake up downstream circuitry.

While in wake-up mode, all registers and the FIFO have normal read/write functionality, and real-time data can be read from the data registers at the reduced wake-up rate. However, no new data is stored in the FIFO during wake-up mode, and there are no interrupts available in wake-up mode.

Standby

Placing the [ADXL372](#) in standby mode suspends measurement and reduces current consumption to less than 100 nA. All interrupts are cleared, and no new interrupts are generated. The [ADXL372](#) powers up in standby mode with all sensor functions turned off.

BANDWIDTH

Low-Pass Antialiasing Filter

High *g* events often include acceleration content over a wide range of frequencies. The analog-to-digital converter (ADC) of the [ADXL372](#) samples the input acceleration at the user selected ODR. In the absence of antialiasing filters, input signals whose frequency is more than half the ODR alias or that fold into the measurement bandwidth can lead to inaccurate measurements. To mitigate this inaccuracy, a four-pole, low-pass filter is provided at the input of the ADC. The filter bandwidth is user selectable, and the default bandwidth is 200 Hz. The maximum bandwidth is constrained to at most half of the ODR, to ensure that the Nyquist criteria is not violated.

High-Pass Filter

The ADXL372 offers a one-pole, high-pass filter with a user selectable –3 dB frequency. Applications that do not require dc acceleration measurements can use the high-pass filter to minimize constant or slow varying offset errors including initial bias, bias drift due to temperature, and bias drift due to supply voltage.

The high-pass filter is a first-order infinite impulse response (IIR) filter. Table 7 lists the available –3 dB frequencies, which are user selectable and dependent on the output data rate. The high-pass and low-pass filters can be used simultaneously to set up a band-pass option.

Table 7. High-Pass Filter –3 dB Corner Frequencies

Setting	ODR (Hz)				
	6400	3200	1600	800	400
00	30.48	15.24	7.61	3.81	1.9
01	15.58	7.79	3.89	1.94	0.97
10	7.88	3.94	1.97	0.98	0.49
11	3.96	1.98	0.99	0.49	0.24

Filter Settling Time

After entering measurement mode, the first output value does not appear until after the filter settling time has passed. This time is selectable using the FILTER_SETTLE bit in the POWER_CTL register. The recommended (and default) settling time to acquire valid data when using either the high-pass filter or the low-pass activity detect filter is 370 ms. The filter settling time of 16 ms is ideal for when both the high-pass filter and low-pass activity detect filter are disabled.

Selectable ODR

The ADXL372 can report acceleration data at 400 Hz, 800 Hz, 1600 Hz, 3200 Hz, or 6400 Hz. The ODR is user selectable and the default is 400 Hz. In the event that the user selects an anti-aliasing filter bandwidth greater than half the ODR, the device defaults the bandwidth to half the ODR. Increasing or decreasing the ODR increases or decreases the current consumption accordingly, as shown in Figure 30.

Table 8. Noise and Current Consumption for $V_s = 2.5\text{ V}$

Mode	Typical RMS Noise (LSB)	Typical Current Consumption (μA)
Normal Operation ¹	3.5	22
Low Noise ¹	3	33

¹ $V_s = 2.5\text{ V}$, ODR = 3200 Hz, and bandwidth = 1600 Hz.

Mode	Typical RMS Noise (LSB)	Typical Current Consumption (μA)
Normal Operation ¹	3	32
Low Noise ¹	2.5	44

¹ $V_s = 3.5\text{ V}$, ODR = 3200 Hz, and bandwidth = 1600 Hz.

Figure 30. Measurement Mode Current vs. ODR for Five Parts

POWER/NOISE TRADE-OFF

The noise performance of the ADXL372 in normal operation, typically 3.5 LSB rms at 3200 Hz ODR and 1600 Hz bandwidth, is adequate for most applications, depending on bandwidth and the desired resolution. For cases where lower noise is needed, the ADXL372 provides a lower noise operating mode that trades reduced noise for a somewhat higher current consumption. In all cases, operating at a higher bandwidth setting increases the rms noise and operating with a lower bandwidth decreases the noise. Table 8 lists the current consumption and noise densities obtained for normal operation and the lower noise mode at a typical 2.5 V supply.

Operating the ADXL372 at a higher supply voltage also decreases noise. Table 9 lists the current consumption and noise densities obtained for normal operation and the lower noise mode at the highest recommended supply, 3.5 V.

POWER SAVINGS

The digital interface of the [ADXL372](#) is implemented with system level power savings in mind. The following features enhance power savings:

- Burst reads and writes reduce the number of SPI communication cycles required to configure the device and retrieve data.
- Concurrent operation of activity and inactivity detection enables set it and forget it operation. Loop modes further reduce communications power by enabling the clearing of interrupts without processor intervention.
- The FIFO is implemented such that consecutive samples can be read continuously via a multibyte read of unlimited length; thus, one FIFO read instruction can clear the entire contents of the FIFO. The [ADXL372](#) FIFO construction also allows the use of direct memory access (DMA) to read the FIFO contents.

AUTONOMOUS EVENT DETECTION

ACTIVITY AND INACTIVITY

The [ADXL372](#) features built in logic that detects activity (defined as acceleration above a user set threshold) and inactivity (defined as acceleration below a user set threshold). Activity and inactivity events can be used as triggers to manage the accelerometer operating mode, trigger an interrupt to a host processor, and/or autonomously drive a motion switch.

Detection of an activity or inactivity event is indicated in the STATUS2 register and can be configured to generate an interrupt. In addition, the activity status of the device, that is, whether it is moving or stationary, is indicated by the AWAKE bit, described in the Using the AWAKE Bit section.

Activity and inactivity detection can be used when the accelerometer is in either measurement mode or wake-up mode. However, the activity and inactivity interrupts are not available in wake-up mode because the device is inherently looking for activity in this mode, and any changes to activity or inactivity detection features must be made while the device is in standby mode.

Low-Pass Activity Detect Filter

The [ADXL372](#) combines high g impact detection and low g movement detection in one device. For low g detection, an internal low-pass filter with a -3 dB corner of approximately 10 Hz averages data to reduce the rms noise, allowing accurate detection of activity or inactivity thresholds as low as 500 mg. For high g impact detection, the low-pass activity detect filter can be turned off through a register setting. When using both the low-pass activity detect filter and the high-pass filter, the user must select a high-pass filter corner that does not exceed 10 Hz; otherwise, activity detection data is severely attenuated.

Activity Detection

An activity event is detected when acceleration in at least one enabled axis remains above a specified threshold for a specified time. Enabled axes, thresholds, and time are user selected. Each axis has its own activity threshold, but the activity timer is shared among all three axes. When multiple axes are selected, an over-threshold event on any one enabled axis triggers the activity detection.

Referenced and Absolute Configurations

Activity detection can be configured as referenced or absolute mode for all axes through the ACT_REF bit in the THRESH_ACT_X_L register.

When using absolute activity detection, acceleration samples are compared directly to a user set threshold to determine whether motion is present. For example, if a threshold of 0.5 g is set and the acceleration on the z-axis is 1 g longer than the user defined activity time, the activity status asserts.

In many applications, it is advantageous for activity detection to be based not on an absolute threshold, but on a deviation from a reference point or orientation. The referenced activity detection is particularly useful because it removes the effect on activity detection of the static 1 g imposed by gravity as well as any static offset errors, which can be up to several g . In absolute activity detection, when the threshold is set to less than 1 g , activity is immediately detected in this case.

In the referenced configuration, activity is detected when acceleration samples are above an internally defined reference by a user defined amount for the user defined amount of time, as described by

$$Abs(Acceleration - Reference) > Threshold$$

where Abs is the absolute value.

Consequently, activity is detected only when the acceleration has deviated sufficiently from the initial orientation. The default setting for the accelerometer is in absolute mode. After it is placed in referenced mode through the appropriate register setting, the reference for activity detection is calculated as soon as full bandwidth measurement mode is turned on. To reset the reference, it is necessary to put the device back into absolute mode and then back to referenced mode. The new reference is set as soon as the device enters full bandwidth measurement mode again. If using both activity and inactivity detection in referenced mode, both must be set back to absolute mode before the reference can be reset.

Activity Timer

Ideally, the intent of activity detection is to wake up a system only when motion is intentional, ignoring noise or small, unintentional movements. In addition to being sensitive to low g events, the [ADXL372](#) activity detection algorithm is robust in filtering out undesired triggers.

The [ADXL372](#) activity detection functionality includes a timer to filter out unwanted motion and ensure that only sustained motion is recognized as activity. The timer period depends on the ODR selected. At 3200 Hz and below, it is ~ 6.6 ms; at 6400 Hz, it is ~ 3.3 ms. For activity detection to trigger, above threshold activity must be sustained for a time equal to the number of activity timer periods specified in the activity time register. For example, a setting of 10 in this register means that above threshold activity must be sustained for 66 ms at 3200 Hz ODR. A register value of zero results in single sample activity detection. The maximum allowable activity time is ~ 1.68 sec (or 841.5 ms at 6400 Hz ODR). Note that the activity timer is operational in measurement mode only.

Activity Detection in Wake-Up Mode

If activity detection is enabled while the device is in wake-up mode, the device uses single sample activity detection, no matter the activity time register setting. If activity is detected, the device automatically returns to full bandwidth measurement mode. However, the activity interrupt is not generated unless the activity time setting is zero. If it is not zero, after entering measurement mode, the interrupt is not generated until the device sees sustained activity for the amount of time given in the activity time register. The awake interrupt automatically goes high upon entering measurement mode if the device is in default mode or autosleep mode. If it is in linked or loop mode (but not autosleep), it is linked to the activity interrupt, which behaves as previously mentioned.

After the device automatically enters measurement mode due to activity detection, if autosleep is not on, it must be placed manually back into wake-up mode.

Inactivity Detection

An inactivity event is detected when acceleration in all enabled axes remains below a specified threshold for a specified time. Enabled axes, threshold, and time are user selected. Each axis has its own inactivity threshold, but the inactivity timer is shared among all three axes. When multiple axes are selected, all enabled axes must stay under the threshold for the required amount of time to trigger inactivity detection.

Referenced and Absolute Configurations

Inactivity detection is also configurable as referenced or absolute through the INACT_REF bit in the THRESH_INACT_X_L register. When using absolute inactivity detection, acceleration samples are compared directly to a user set threshold for the user set time to determine the absence of motion. Inactivity is detected when enough consecutive samples are all below the threshold.

When using referenced inactivity detection, inactivity is detected when acceleration samples are within a user specified amount from an internally defined reference for a user defined amount of time.

$$Abs(Acceleration - Reference) < Threshold$$

Referenced inactivity, like referenced activity, is particularly useful for eliminating the effects of the static acceleration due to gravity, as well as other static offsets. With absolute inactivity, if the inactivity threshold is set lower than 1 g, a device resting motionless may never detect inactivity. With referenced inactivity, the same device under the same configuration detects inactivity. The default setting for the accelerometer is in absolute mode. After it is placed in referenced mode through the appropriate register setting, the reference for inactivity detection is calculated as soon as full bandwidth measurement mode is turned on. To reset the reference, it is necessary to put the device back into absolute mode and then back to referenced mode. The new reference is set as soon as the device enters full bandwidth measurement mode again. If using both inactivity and activity detection in referenced mode, both must be set back to absolute mode before the reference can be reset.

Inactivity Timer

The ADXL372 inactivity detect functionality includes a timer to allow detection of sustained inactivity. The timer period depends on the ODR selected. At 3200 Hz and below, it is ~26 ms; at 6400 Hz, it is ~13 ms. For inactivity detection to trigger, below threshold inactivity must be sustained for a time equal to the number of inactivity timer periods specified in the inactivity time registers. For example, a setting of 10 in these registers means that below threshold inactivity must be sustained for 260 ms at 3200 Hz ODR. A value of zero in these registers results in single sample, inactivity detection. The maximum allowable inactivity time is ~28.4 minutes at 3200 Hz ODR (or ~14.2 minutes at 6400 Hz ODR).

Linking Activity and Inactivity Detection

When in measurement mode or wake-up mode, the activity and inactivity detection functions can be used concurrently and processed manually by a host processor, or they can be configured to interact in several other ways, such as those that follow.

Default Mode

In default mode, activity and inactivity detection are both available simultaneously, and all interrupts must be serviced by a host processor; that is, a processor must read each interrupt before it is cleared and can be used again. Refer to the Interrupts section for information on clearing interrupts.

The flowchart in Figure 31 illustrates default mode operation.

NOTES
 1. THE AWAKE BIT DEFAULTS TO 1 WHEN ACTIVITY AND INACTIVITY ARE NOT LINKED.

Figure 31. Flowchart Illustrating Activity and Inactivity Operation in Default Mode

Linked Mode

In linked mode, activity and inactivity detection are linked to each other such that only one of the functions is enabled at any given time. As soon as activity is detected, the device is assumed to be moving (or awake) and stops looking for activity; rather, inactivity is expected as the next event. Therefore, only inactivity detection operates.

Similarly, when inactivity is detected, the device is assumed to be stationary (or asleep). Thus, activity is expected as the next event; therefore, only activity detection operates.

In linked mode, each interrupt must be serviced by a host processor before the next interrupt is enabled.

The flowchart in Figure 32 illustrates linked mode operation.

Figure 32. Flowchart Illustrating Activity and Inactivity Operation in Linked Mode

Loop Mode

In loop mode, motion detection operates as described in the Linked Mode section, but interrupts do not need to be serviced by a host processor. This configuration simplifies the implementation of commonly used motion detection and enhances power savings by reducing the amount of power used in bus communication.

The flowchart in Figure 33 illustrates loop mode operation.

Figure 33. Flowchart Illustrating Activity and Inactivity Operation in Loop Mode

Autosleep

If autosleep is selected, after the device is placed in wake-up mode (see the Wake-Up Mode section), it automatically sets to loop mode and begins looking for activity. When activity is detected, the device automatically enters measurement mode and immediately begins looking for inactivity. When inactivity is detected, the device automatically re-enters wake-up mode. Note that the device must be manually placed in wake-up mode before autosleep can begin functioning. It does not automatically enter wake-up mode if the device is started up manually in measurement mode.

Using the AWAKE Bit

The AWAKE bit is a status bit that indicates whether the ADXL372 is awake or asleep. In default mode or autosleep mode, the AWAKE bit is high whenever the device is in measurement mode. In linked or loop mode, the AWAKE bit is high whenever the device experiences an activity condition, and it is low when the device experiences an inactivity condition.

The awake signal can be mapped to the INT1 or the INT2 pin allowing the pin to serve as a status output to connect or disconnect power to downstream circuitry based on the awake status of the accelerometer. Used in conjunction with loop mode, this configuration implements a simple, autonomous motion activated switch.

If the turn-on time of downstream circuitry can be tolerated, this motion switch configuration can save significant system level power by eliminating the standby current consumption of the remainder of the application circuit. This standby current can often exceed the full operating current of the ADXL372.

MOTION WARNING

In addition to the activity threshold previously described, the ADXL372 offers a secondary threshold. This second threshold, the motion warning threshold, can be set independently of the activity threshold. It does not have any functionality related to autosleep, linked, or loop mode, or the device awake status. The purpose of the motion warning functionality is to issue a notification to the system, via the status bit and/or interrupt, that the observed acceleration has exceeded the second threshold. It is controlled by the THRESH_ACT2_x_x registers, and by the ACTIVITY2 interrupt, which is sent only to the INT2 pin. Each axis has its own motion warning threshold. However, the motion warning activity interrupt does not have an activity timer. It is only used for single sample, activity detection. The motion warning threshold also shares the same referenced vs. absolute configuration as the primary activity detection.

IMPACT DETECTION FEATURES

Impact detection applications often require high g and high bandwidth acceleration measurements, and the ADXL372 is designed with these applications in mind. Several features are included that target impact detection and aim to simplify the system design.

WIDE BANDWIDTH

An impact is a transient event that produces an acceleration pulse with frequency content over a wide range. A sufficiently wide bandwidth is needed to capture the impact event because lowering bandwidth has the effect of reducing the magnitude of the recorded signal, resulting in measurement inaccuracy.

The ADXL372 can operate with bandwidths of up to 3200 Hz at extremely low power levels. A steep filter roll-off is also useful for effective suppression of out of band content, and the ADXL372 incorporates a four-pole, low-pass antialiasing filter for this purpose.

INSTANT ON IMPACT DETECTION

The ADXL372 instant on mode is an ultralow power mode that continuously monitors the environment for impact events that exceed a built in threshold. When an impact is detected, the device switches into full measurement mode and captures the impact profile.

User must enter instant on mode from full bandwidth measurement mode with 16 ms delay before the first valid data gets ready. No digital data is available in this mode of operation. The user can configure the device to detect an impact between a threshold level of either 10 g to 15 g or 30 g to 40 g by using the INSTANT_ON_THRESH bit in the POWER_CTL register. When an impact beyond the selected threshold is detected, the ADXL372 switches to full bandwidth measurement mode and begins outputting digital data.

Figure 34. Instant On Mode Using Default Threshold

After the accelerometer is in full bandwidth measurement mode, it must be set back into instant on mode manually. It cannot return to instant on mode automatically.

CAPTURING IMPACT EVENTS

In certain applications, a single (3-axis) acceleration sample at the peak of an impact event contains sufficient information about the event, and the full acceleration history is not required. For these applications, the ADXL372 provides the capability to store only the peak acceleration of each over threshold event. The x , y , and z acceleration samples at the peak of the event can be stored in the FIFO. Applications that do not require the full event profile can greatly increase the time between FIFO reads by storing only peak acceleration information. A peak is defined as the x , y , and z acceleration sample that has the highest magnitude (root sum squared) of all other values within a particular over threshold event. In addition to recording the peak of each over threshold impact event in the FIFO, the ADXL372 can also keep track of the absolute highest peak recorded in separate registers.

Figure 35. Capturing Impact Events

Enable peak detection by doing the following:

- Put the FIFO in peak detect and stream mode (b0011101x to Register 0x3A).
- Set the desired activity threshold and time settings (Register 0x23 to Register 0x29).
- Set the desired inactivity threshold and time settings (Register 0x2A to Register 0x31).
- Set the activity mode to linked or loop mode (Register 0x3E).

As soon as the activity interrupt is triggered, the device records the x , y , and z values of the peak acceleration event that occurs between the activity interrupt trigger and the next inactivity interrupt trigger, as shown in Figure 35 in the FIFO. It continues to do this for each period of activity between the triggering of the activity interrupt and consequent triggering of the inactivity interrupt. The process does work in linked mode, but the user must be clear each interrupt before the device looks for the next activity or inactivity interrupt. For as long as peak detect mode is selected, the device also stores the highest overall peak recorded in the MAXPEAK_x_x registers. When these values are read out of the registers, the register data is cleared, and the device begins looking for the new highest peak.

FIFO

The ADXL372 includes a deep, 512 sample FIFO buffer.

BENEFITS OF THE FIFO

The FIFO buffer is an important feature in ultralow power applications in two ways: system level power savings and data recording/event context.

System Level Power Savings

Appropriate use of the FIFO enables system level power savings by enabling the host processor to sleep for extended periods while the accelerometer autonomously collects data. Alternatively, using the FIFO to collect data can unburden the host while it tends to other tasks.

Data Recording/Event Context

The FIFO can be used in a triggered mode to record all data leading up to an activity detection event, thereby providing context for the event. In the case of a system that identifies impact events, for example, the accelerometer can keep the entire system off while it stores acceleration data in its FIFO and looks for an activity event. When the impact event occurs, data collected prior to the event is frozen in the FIFO. The accelerometer can now wake the rest of the system and transfer this data to the host processor, thereby providing context for the impact event.

Generally, the more context available, the more intelligent decisions a system can achieve, making a deep FIFO especially useful. For example, the ADXL372 FIFO can store up to 512 1-axis samples at 400 Hz ODR, providing a 1.28 sec window, or 170 3-axis samples at 3200 Hz to provide a 50 ms window, which is a typical duration for impact events.

USING THE FIFO

The FIFO is a 512 sample memory buffer that can save power, unburden the host processor, and autonomously record data.

FIFO operation is configured via Register 0x39 and Register 0x3A. The 512 FIFO samples can be allotted in several ways, such as the following:

- 170 sample sets of concurrent 3-axis data
- 256 sample sets of concurrent 2-axis data (user selectable)
- 512 sample sets of single-axis data
- 170 sets of impact event peak (x, y, z)

All FIFO modes must be configured while in standby mode. When reading data from multiple axes from the FIFO, to ensure that data is not overwritten and stored out of order, at least one sample set must be left in the FIFO after every read (therefore, a set of 3-axis data must have 169 samples at most).

The FIFO operates in one of the following four modes: FIFO disabled, oldest saved mode (first N), stream mode (last N), and triggered mode.

FIFO Disabled

When the FIFO is disabled, no new data is stored in it, and any data already in it is cleared.

The FIFO is disabled by setting the FIFO_MODE bits in the FIFO_CTL register (Register 0x3A) to 0b00.

Oldest Saved Mode (First N)

In oldest saved mode, the FIFO accumulates data until it is full and then stops. After reading the data, the FIFO must be disabled and re-enabled to save a new set of data. One possible use case for this mode is to enable it right after entering instant on mode. After a shock is detected, the data immediately stores in the FIFO to be read whenever convenient.

The FIFO is placed into oldest saved mode by setting the FIFO_MODE bits in the FIFO_CTL register (Register 0x3A) to 0b11.

Stream Mode (Last N)

In stream mode, the FIFO always contains the most recent data. The oldest sample is discarded when space is needed to make room for a newer sample.

Stream mode is useful for unburdening a host processor. The processor can tend to other tasks while data is being collected in the FIFO. When the FIFO fills to a certain number of samples (specified by the FIFO_SAMPLES register along with Bit 0 in the FIFO_CTL register), it triggers a watermark interrupt (if this interrupt is enabled). At this point, the host processor can read the contents of the entire FIFO and then return to its other tasks as the FIFO fills again.

The FIFO is placed into stream mode by setting the FIFO_MODE bits in the FIFO_CTL register (Register 0x3A) to 0b01.

Triggered Mode

In triggered mode, the FIFO operates as in stream mode until an activity detection event, after which it saves the samples surrounding that event. The operation is similar to a one-time run trigger on an oscilloscope. The number of samples to be saved after the activity event is specified in FIFO_SAMPLES (Register 0x39[7:0], along with Bit 0 in the FIFO_CTL register, Register 0x3A). For example if the FIFO_SAMPLE is set to 12, there are 500 samples before the trigger and 12 after the trigger. The trigger can be reset by clearing the activity interrupt and reading all 512 locations of the FIFO. If this is not complete, future FIFO data reads may contain invalid data. Place the FIFO into triggered mode by setting the FIFO_MODE bits in the FIFO_CTL register (Register 0x3A) to 0b10.

RETRIEVING DATA FROM FIFO

Access FIFO data by reading the FIFO_DATA register. A multibyte read to this register does not auto-increment the address, and instead continues to pop data from the FIFO. Data is left justified and formatted as shown in Table 10.

When reading data, the most significant byte (Bits[B15:B8]) is read first, followed by the least significant byte (Bits[B7:B0]). Bits[B15:B4] represent the 12-bit, twos complement acceleration data. Bit 0 serves as a series start indicator: only the first data byte of a series contains a 1 in this bit, and the remaining items contain a 0.

Table 10. FIFO Buffer Data Format

INTERRUPTS

Several of the built in functions of the ADXL372 can trigger interrupts to alert the host processor of certain status conditions. The functionality of these interrupts is described in this section.

INTERRUPT PINS

Interrupts can be mapped to either (or both) of two designated output pins, INT1 and INT2, by setting the appropriate bits in the INT1_MAP register and INT2_MAP register, respectively. All functions can be used simultaneously. If multiple interrupts are mapped to one pin, the OR combination of the interrupts determines the status of the pin.

If no functions are mapped to an interrupt pin, that pin is automatically configured to a high impedance (high-Z) state. The pins are also placed in the high-Z state upon a reset.

When a certain status condition is detected, the pin that condition is mapped to is activated. The configuration of the pin is active high by default so when it is activated, the pin goes high. However, this configuration can be switched to active low by setting the INTx_LOW bit in the appropriate INTx_MAP register.

The INTx pins can connect to the interrupt input of a host processor where interrupts are responded to with an interrupt routine. Because multiple functions can be mapped to the same pin, the STATUS register can determine which condition caused the interrupt to trigger.

Interrupts are cleared in several of the following ways:

- Reading the STATUS2 register clears ACTIVITY and INACT interrupts. However, if activity detection is operating in default mode, and the activity or inactivity timers are set to 0, the only way to clear the activity or inactivity bits, respectively, is to set the device into standby mode and restart full bandwidth measurement mode.
- Setting the device into standby mode and back into full bandwidth measurement mode clears the ACTIVITY2 interrupt.
- Reading from the data registers clears the DATA_RDY interrupt.
- Reading enough data from the FIFO buffer so that interrupt conditions are no longer met, and then reading the STATUS register (Register 0x04) clears the FIFO_RDY, FIFO_FULL, and FIFO_OVR interrupts.

Both interrupt pins are push-pull low impedance pins with an output impedance of about 500 Ω (typical) and digital output specifications as shown in Table 11. Both have bus keepers that hold them to a valid logic state when they are in a high impedance mode.

To prevent interrupts from being falsely triggered during configuration, disable interrupts while their settings, such as thresholds, timings, or other values, are configured.

Alternate Functions

The INT1 and INT2 pins can be configured for use as input pins instead of for signaling interrupts. INT1 is used as an external clock input when the EXT_CLK bit in the TIMING register is set. INT2 is used as the trigger input for synchronized sampling when the EXT_SYNC bit in the TIMING register is set. One or both of these alternate functions can be used concurrently; however, if an interrupt pin is used for its alternate function, it cannot simultaneously be used to signal interrupts.

TYPES OF INTERRUPTS

Activity and Inactivity Interrupts

The ACTIVITY bit and INACT bit are set when activity and inactivity are detected, respectively. Detection procedures and criteria are described in the Autonomous Event Detection section.

Data Ready Interrupt

The DATA_RDY bit is set when new valid data is available, and it is cleared when no new data is available.

The DATA_RDY bit does not set while any of the data registers are being read. If DATA_RDY = 0 prior to a register read and new data becomes available during the register read, DATA_RDY remains 0 until the read is complete and only then sets to 1.

If DATA_RDY = 1 prior to a register read, it is cleared at the start of the register read.

If DATA_RDY = 1 prior to a register read and new data becomes available during the register read, DATA_RDY is cleared to 0 at the start of the register read and remains 0 throughout the read. When the read is complete, DATA_RDY is set to 1.

FIFO Interrupts

FIFO Watermark

The FIFO_FULL bit is set when the number of samples stored in the FIFO is equal to or exceeds the number specified in FIFO_SAMPLES (Register 0x39 together with Bit 0 in the FIFO_CTL register). The FIFO_FULL bit is cleared automatically when enough samples are read from the FIFO, such that the number of samples remaining is lower than that specified.

If the number of FIFO samples is set to 0, the watermark interrupt is set. To avoid unexpectedly triggering this interrupt, the default value of the FIFO_SAMPLES register is 0x80.

FIFO Ready

The FIFO_RDY bit is set when there is at least one valid sample available in the FIFO output buffer. This bit is cleared when no valid data is available in the FIFO. In FIFO triggered mode, it is only set after the activity interrupt is detected, and the data surrounding the event is saved in the FIFO.

Overrun

The FIFO_OVR bit is set when the FIFO has overrun or overflowed, such that new data replaces unread data, which may indicate a full FIFO that has not yet been emptied or a clocking error caused by a slow SPI transaction. If the FIFO is configured to oldest saved mode, an overrun event indicates that there is insufficient space available for a new sample.

The FIFO_OVR bit is cleared when both the contents of the FIFO and the STATUS register are read. It is also cleared when the FIFO is disabled.

Table 11. Interrupt Pin Digital Output

Parameter	Test Conditions	Limit ¹		Unit
		Min	Max	
Digital Output				
Low Level Output Voltage (V_{OL})	$I_{OL} = 500 \mu A$		$0.2 \times V_{DDI/O}$	V
High Level Output Voltage (V_{OH})	$I_{OH} = -300 \mu A$	$0.8 \times V_{DDI/O}$		V
Low Level Output Current (I_{OL})	$V_{OL} = V_{OL, MAX}$	500		μA
High Level Output Current (I_{OH})	$V_{OH} = V_{OH, MIN}$		-300	μA
Pin Capacitance	$f_{IN} = 1 \text{ MHz}, V_{IN} = 2.0 \text{ V}$		8	pF
Rise/Fall Time				
Rise Time (t_R) ²	$C_{LOAD} = 150 \text{ pF}$		210	ns
Fall Time (t_F) ³	$C_{LOAD} = 150 \text{ pF}$		150	ns

¹ Limits based on characterization results, not production tested.

² Rise time is measured as the transition time from $V_{OL, MAX}$ to $V_{OH, MIN}$ of the interrupt pin.

³ Fall time is measured as the transition time from $V_{OH, MIN}$ to $V_{OL, MAX}$ of the interrupt pin.

ADDITIONAL FEATURES

USING AN EXTERNAL CLOCK

When operating at 3200 Hz ODR or lower, the [ADXL372](#) has a built in 307.2 kHz (typical) clock that, by default, serves as the time base for internal operations. At 6400 Hz ODR, this clock speed increases to 614.4 kHz (typical). If desired, an external clock can be provided instead, for either improved clock frequency accuracy or for control of the output data rate. To use an external clock, set the EXT_CLK bit (Bit 1) in the TIMING register (Register 0x3D) and apply a clock to the INT1 pin.

The external clock can operate at the nominal 307.2 kHz or slower (when using $ODR \leq 3200$ Hz), or 614.4 kHz or slower (when using $ODR = 6400$ Hz) to allow the user to achieve any desired output data rate. Lower external clock rates must be used with caution because it may result in aliasing of high frequency signals that may be present in certain applications.

ODR and bandwidth scale proportionally with the clock. The [ADXL372](#) provides a discrete number of options for ODR. ODRs other than those provided are achieved by selecting an appropriate clock frequency. For example, to achieve a 2560 Hz ODR, use the 3200 Hz setting with a clock frequency that is 80% of nominal, or 245.76 kHz. Bandwidth also scales by the same ratio, so if a 400 Hz bandwidth is selected, the resulting bandwidth is 320 Hz.

SYNCHRONIZED DATA SAMPLING

For applications that require a precisely timed acceleration measurement, the [ADXL372](#) features an option to synchronize acceleration sampling to an external trigger. The EXT_SYNC bit in the TIMING register enables this feature. When the EXT_SYNC bit is set to 1, the INT2 pin automatically reconfigures for use as the sync trigger input.

When external triggering is enabled, it is up to the system designer to ensure that the sampling frequency meets system requirements. Sampling too infrequently causes aliasing. Noise can be lowered by oversampling; however, sampling at too high a frequency may not allow enough time for the accelerometer to process the acceleration data and convert it to valid digital output data.

When the Nyquist criterion is met, signal integrity is maintained. An internal antialiasing filter is available in the [ADXL372](#) and can assist the system designer in maintaining signal integrity. To prevent aliasing, set the filter bandwidth to a frequency no greater than half the sampling rate. For example, when sampling at 1600 Hz, set the filter bandwidth to no higher than 800 Hz.

Because of internal timing requirements, the maximum allowable external trigger frequencies are as follows:

- 1-axis data = 3100 Hz
- 2-axis data = 2700 Hz
- 3-axis data = 2200 Hz

These values are doubled when an ODR rate of 6400 Hz is selected. Additionally, the trigger signal applied to the INT2 pin must meet the following criteria:

- The trigger signal must be active high.
- The pulse width of the trigger signal must be at least 53 μ s.
- The minimum sampling frequency is set only by system requirements. Samples need not be polled at any minimum rate; however, if samples are polled at a rate lower than the bandwidth set by the antialiasing filter, aliasing may occur.

The EXT_SYNC is an active high signal. Due to the asynchronous nature of the internal clock and external sync, there may be a one ODR clock cycle difference between consecutive external sync pulses. The external sync sets the ODR of the system. For example, if sending an external sync at a 2 kHz rate, all 3 axes (if enabled) are sampled in that 2 kHz window.

SELF TEST

The [ADXL372](#) incorporates a pass or fail self test feature that effectively tests its mechanical and electronic systems simultaneously. When the self test function is invoked, an electrostatic force is applied to the mechanical sensor. This electrostatic force moves the mechanical sensing element in the same manner as acceleration, and the acceleration experienced by the device increases because of this force.

Self Test Procedure

The self test function is enabled via the ST bit in the SELF_TEST register, Register 0x40. The recommended procedure for using the self test functionality is as follows:

1. Place the device into measurement mode.
2. Make sure the low-pass activity filter is enabled.
3. Assert self test by setting the ST bit in the SELF_TEST register (Register 0x40).

Read the self test status bits, ST_DONE and USER_ST, after approximately 300 ms to check the pass or fail condition.

USER REGISTER PROTECTION

The ADXL372 includes user register protection for single event upsets (SEUs). An SEU is a change of state caused by ions or electromagnetic radiation striking a sensitive node in a micro-electronic device. The state change is a result of the free charge created by ionization in or close to an important node of a logic element (for example, a memory bit). The SEU itself is not considered permanently damaging to transistor or circuit functionality, but can create erroneous register values. The registers protected from SEU are Register 0x20 to Register 0x3F.

Protection is implemented via a 99-bit error correcting (Hamming type) code and detects both single bit and double bit errors. The check bits are recomputed any time a write to any of the protected registers occurs. At any time, if the stored version of the check bits is not in agreement with the current check bit calculation, the ERR_USER_REGS status bit is set.

The ERR_USER_REGS bit in the STATUS register starts high when set on an unconfigured device and clears upon the first register write.

USER OFFSET TRIMS

The ADXL372 has a 4-bit offset trim for each axis that allows users to add positive or negative offset to the default static acceleration values and correct any deviations from ideal that may result as a consequence of varying the operating parameters of the device. The offset trims have a full-scale range of about ± 60 LSB with a trim profile as shown in Figure 36.

Figure 36. User Offset Trim Profile

SERIAL COMMUNICATIONS

SERIAL INTERFACE

The ADXL372 is designed to communicate in either the SPI or the I²C protocol. It autodetects the format being used, requiring no configuration control to select the format.

SPI Protocol

The timing scheme is as follows: CPHA = CPOL = 0. The ADXL372 supports a SCLK frequency up to 10 MHz. Wire the ADXL372 for SPI communication as shown in Figure 37. For successful communication, follow the logic thresholds and timing parameters in Table 12. The command structure for the read register and write register are shown in Figure 40 and Figure 41, respectively. The read and write register commands support multibyte (burst) read/write access. The waveform diagrams for multibyte read and write commands are shown in Figure 42 and Figure 43, respectively.

Ignore data transmitted from the ADXL372 to the master device during writes to the ADXL372.

Figure 37. 4-Wire SPI Connection Diagram

I²C Protocol

The ADXL372 supports point to point I²C communication. However, for devices with REVID = 0x02, when sharing an SDA bus, the ADXL372 may prevent communication with other devices on that bus. If at any point, even when the ADXL372 is not being addressed, the 0x3A or 0x3B bytes (when the ADXL372 Device ID is set to 0x1D), or the 0xA6 or 0xA7 bytes (when the ADXL372 Device ID is set to 0x53) are transmitted on the SDA bus, the ADXL372 responds with an acknowledge bit and pulls the SDA line down. For example, this can happen when reading or writing the data bytes to another sensor on the bus. When the ADXL372 pulls the SDA line down, communication with other devices on the bus may be interrupted. To work around this issue, the ADXL372 must be connected to a separate SDA bus, or the SCLK pin must be switched high when communication with the ADXL372 is not desired (it must be normally grounded).

The ADXL372 supports standard (100 kHz), fast (up to 1 MHz), and high speed (up to 3.4 MHz) data transfer modes if the bus parameters given in Table 13 are met. There is no minimum SCL frequency, with the exception that when reading data, the clock must be fast enough to read an entire sample set before new data overwrites it. Single byte or multibyte reads/writes are supported. With the MISO pin low, the I²C address for the device is 0x1D, and an alternate I²C address of 0x53 can be chosen by pulling the MISO pin high.

There are no internal pull-up or pull-down resistors for any unused pins; therefore, there is no known state or default state for the pins if left floating or unconnected. It is a requirement that SCLK be connected to ground when communicating to the ADXL372 using the I²C.

Due to communication speed limitations, the maximum output data rate when using 400 kHz I²C is 800 Hz and scales linearly with a change in the I²C communication speed. For example, using I²C at 100 kHz limits the maximum ODR to 200 Hz. Operation at an output data rate above the recommended maximum can result in undesirable effect on the acceleration data, including missing samples or additional noise.

Figure 38. I²C Connection Diagram (ADXL372 Device ID = 0x53)

If other devices are connected to the same I²C bus, the nominal operating voltage level of these other devices cannot exceed V_{DDIO} by more than 0.3 V. External pull-up resistors, R_P , are necessary for proper I²C operation. Single byte or multibyte reads/writes are supported, as shown from Figure 45 to Figure 47.

MULTIBYTE TRANSFERS

Both the SPI and I²C protocols support multibyte transfers, also known as burst transfers. A register read or write begins with the address specified in the command and auto-increments for each additional byte in the transfer. Always read acceleration data using multibyte transfers to ensure a concurrent and complete set of x-, y-, and z-acceleration data is read.

The FIFO runs on the serial port clock during FIFO reads and can sustain bursting at the SPI clock rate as long as the SPI clock is 1 MHz or faster.

The address auto-increment function is disabled when the FIFO address is used, which is so that data can be read continuously from the FIFO as a multibyte transaction. In cases where the starting address of a multibyte transaction is less than the FIFO address, the address auto-increments until the FIFO address is reached, and then it stops at the FIFO address.

When writing data to the ADXL372 in I²C mode, the no acknowledge (NACK) is never generated. Instead, the acknowledge (ACK) bit is sent after every received byte because it is not known how many bytes are included in the transfer. The master decides how many bytes are sent and ends the transaction with the stop condition.

INVALID ADDRESSES AND ADDRESS FOLDING

The ADXL372 has a 6-bit address bus, mapping only 104 registers in the possible 256 register address space. The addresses do not fold to repeat the registers at addresses above 0x104. Attempted access to register addresses above 0x104 are mapped to the invalid register at 0x67 and have no functional effect.

Register 0x00 to Register 0x42 are for customer access, as described in Table 14. Register 0x43 to Register 0x67 are reserved for factory use.

T_A = 25°C, V_S = 2.5 V, V_{DDI/O} = 2.5 V, unless otherwise noted.

Table 12. SPI Logic Levels and Timing

Parameter	Description	Min	Typ	Max	Unit

REGISTER DETAILS

ANALOG DEVICES ID REGISTER

Address: 0x00, Reset: 0xAD, Name: DEVID_AD

This register contains the Analog Devices, Inc., ID, 0xAD.

Table 15. Bit Descriptions for DEVID_AD

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	DEVID_AD		Analog Devices ID, 0xAD.	0xAD	R

ANALOG DEVICES MEMS ID REGISTER

Address: 0x01, Reset: 0x1D, Name: DEVID_MST

This register contains the Analog Devices MEMS ID, 0x1D.

Table 16. Bit Descriptions for DEVID_MST

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	DEVID_MST		Analog Devices MEMS ID, 0x1D.	0x1D	R

DEVICE ID REGISTER

Address: 0x02, Reset: 0xFA, Name: PARTID

This register contains the device ID, 0xFA (372 octal).

Table 17. Bit Descriptions for PARTID

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	DEVID_PRODUCT		Device ID, 0xFA (372 Octal).	0xFA	R

PRODUCT REVISION ID REGISTER

Address: 0x03, Reset: 0x02, Name: REVID

This register contains the mask revision ID, beginning with 0x00 and incrementing for each subsequent revision.

Table 18. Bit Descriptions for REVID

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	REVID		Mask revision.	0x2	R

STATUS REGISTER

Address: 0x04, Reset: 0xA0, Name: STATUS

This register includes the following bits that describe various conditions of the ADXL372.

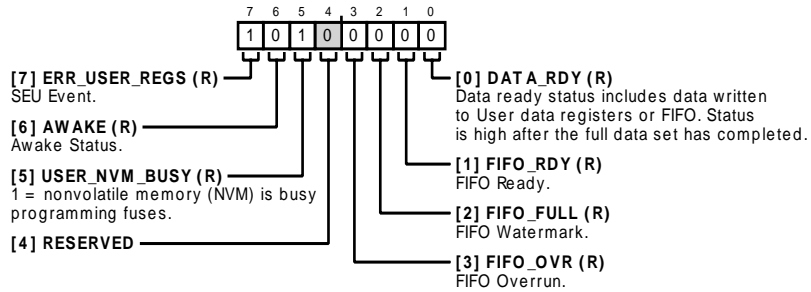

Table 19. Bit Descriptions for STATUS

Bits	Bit Name	Settings	Description	Reset	Access
7	ERR_USER_REGS		SEU Event. An SEU event has been detected in a user register.	0x1	R
6	AWAKE		Awake Status. Activity has been detected and the device is moving.	0x0	R
5	USER_NVM_BUSY		1 = nonvolatile memory (NVM) is busy programming fuses.	0x1	R
4	RESERVED		Reserved.	0x0	R
3	FIFO_OVR		FIFO Overrun. FIFO has overflowed, and data has been lost.	0x0	R
2	FIFO_FULL		FIFO Watermark. The FIFO watermark level, specified in FIFO_SAMPLES, has been reached.	0x0	R
1	FIFO_RDY		FIFO Ready. At least one valid sample is available in the FIFO.	0x0	R
0	DATA_RDY		Data ready status includes data written to user data registers or FIFO. Status is high after the full data set has completed. A complete x, y, and z measurement has been made and results can be read.	0x0	R

ACTIVITY STATUS REGISTER

Address: 0x05, Reset: 0x00, Name: STATUS2

Table 20. Bit Descriptions for STATUS2

Bits	Bit Name	Settings	Description	Reset	Access
7	RESERVED		Reserved.	0x0	R
6	ACTIVITY2		Status of ACTIVITY2.	0x0	R
5	ACTIVITY		Activity. Activity has been detected.	0x0	R
4	INACT		Inactivity. Inactivity has been detected.	0x0	R
[3:0]	RESERVED		Reserved.	0x0	R

FIFO ENTRIES REGISTER, MSB

Address: 0x06, Reset: 0x00, Name: FIFO_ENTRIES2

The FIFO_ENTRIES2 and FIFO_ENTRIES registers indicate the number of valid data samples present in the FIFO buffer. The number ranges from 0 to 512 or 0x00 to 0x200. FIFO_ENTRIES contains the least significant byte, and FIFO_ENTRIES2 contains the two most significant bits.

Table 21. Bit Descriptions for FIFO_ENTRIES2

Bits	Bit Name	Settings	Description	Reset	Access
[7:2]	RESERVED		Reserved.	0x0	R
[1:0]	FIFO_ENTRIES[9:8]		Number of data samples stored in the FIFO.	0x0	R

FIFO ENTRIES REGISTER, LSB

Address: 0x07, Reset: 0x00, Name: FIFO_ENTRIES

Table 22. Bit Descriptions for FIFO_ENTRIES

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	FIFO_ENTRIES[7:0]		Number of data samples stored in the FIFO.	0x0	R

X-AXIS DATA REGISTER, MSB

Address: 0x08, Reset: 0x00, Name: XDATA_H

These two registers contain the x-axis acceleration data. Data is left justified and formatted as twos complement. XDATA_H contains the eight most significant bits (MSBs), and XDATA_L contains the four least significant bits (LSBs) of the 12-bit value.

Table 23. Bit Descriptions for XDATA_H

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	XDATA[11:4]		X-axis data.	0x0	R

X-AXIS DATA REGISTER, LSB

Address: 0x09, Reset: 0x00, Name: XDATA_L

Table 24. Bit descriptions for XDATA_L

Bits	Bit Name	Settings	Description	Reset	Access
[7:4]	XDATA[3:0]		X-axis data.	0x0	R
[3:0]	RESERVED		Reserved.	0x0	R

Y-AXIS DATA REGISTER, MSB

Address: 0x0A, Reset: 0x00, Name: YDATA_H

The YDATA_H and YDATA_L registers contain the y-axis, LSB acceleration data. Data is left justified and formatted as twos complement. YDATA_H contains the eight most significant bits (MSBs), and YDATA_L contains the four least significant bits (LSBs) of the 12-bit value. YDATA_L latches on a read of YDATA_H to ensure data integrity.

Table 25. Bit Descriptions for YDATA_H

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	YDATA[11:4]		Y-axis data.	0x0	R

Y-AXIS DATA REGISTER, LSB

Address: 0x0B, Reset: 0x00, Name: YDATA_L

Table 26. Bit Descriptions for YDATA_L

Bits	Bit Name	Settings	Description	Reset	Access
[7:4]	YDATA[3:0]		Y-axis data.	0x0	R
[3:0]	RESERVED		Reserved.	0x0	R

Z-AXIS DATA REGISTER, MSB

Address: 0x0C, Reset: 0x00, Name: ZDATA_H

These two registers contain the z-axis acceleration data. Data is left justified and formatted as twos complement. ZDATA_H contains the eight most significant bits (MSBs), and ZDATA_L contains the four least significant bits (LSBs) of the 12-bit value.

Table 27. Bit Descriptions for ZDATA_H

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	ZDATA[11:4]		Z-axis data.	0x0	R

Z-AXIS DATA REGISTER, LSB

Address: 0x0D, Reset: 0x00, Name: ZDATA_L

Table 28. Bit Descriptions for ZDATA_L

Bits	Bit Name	Settings	Description	Reset	Access

[3:0]	RESERVED		Reserved.	0x0	R

HIGHEST PEAK DATA REGISTERS

The highest peak data registers contain the acceleration data corresponding to the highest magnitude sample recorded since the last read of this register. Data is left justified and formatted as twos complement.

X-AXIS HIGHEST PEAK DATA REGISTER, MSB

Address: 0x15, Reset: 0x00, Name: MAXPEAK_X_H

Table 29. Bit Descriptions for MAXPEAK_X_H

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	MAXPEAK_X[11:4]		Stores the highest magnitude observed since the last read of this register. The 8 MSBs of the x-axis value.	0x0	R

X-AXIS HIGHEST PEAK DATA REGISTER, LSB

Address: 0x16, Reset: 0x00, Name: MAXPEAK_X_L

Table 30. Bit Descriptions for MAXPEAK_X_L

Bits	Bit Name	Settings	Description	Reset	Access
[7:4]	MAXPEAK_X[3:0]		Stores the highest magnitude observed since the last read of this register. The 4 LSBs of the x-axis value.	0x0	R
[3:0]	RESERVED		Reserved.	0x0	R

Y-AXIS HIGHEST PEAK DATA REGISTER, MSB

Address: 0x17, Reset: 0x00, Name: MAXPEAK_Y_H

Table 31. Bit Descriptions for MAXPEAK_Y_H

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	MAXPEAK_Y[11:4]		Stores the highest magnitude observed since the last read of this register. The 8 MSBs of the y-axis value.	0x0	R

Y-AXIS HIGHEST PEAK DATA REGISTER, LSB

Address: 0x18, Reset: 0x00, Name: MAXPEAK_Y_L

Table 32. Bit Descriptions for MAXPEAK_Y_L

Bits	Bit Name	Settings	Description	Reset	Access
[7:4]	MAXPEAK_Y[3:0]		Stores the highest magnitude observed since the last read of this register. The 4 LSBs of the y-axis value.	0x0	R
[3:0]	RESERVED		Reserved.	0x0	R

Z-AXIS HIGHEST PEAK DATA REGISTER, MSB

Address: 0x19, Reset: 0x00, Name: MAXPEAK_Z_H

Table 33. Bit Descriptions for MAXPEAK_Z_H

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	MAXPEAK_Z[11:4]		Stores the highest magnitude observed since the last read of this register. The 8 MSBs of the z-axis value.	0x0	R

Z-AXIS HIGHEST PEAK DATA REGISTER, LSB

Address: 0x1A, Reset: 0x00, Name: MAXPEAK_Z_L

Table 34. Bit Descriptions for MAXPEAK_Z_L

Bits	Bit Name	Settings	Description	Reset	Access
[7:4]	MAXPEAK_Z[3:0]		Stores the highest magnitude observed since the last read of this register. The 4 LSBs of the z-axis value.	0x0	R
[3:0]	RESERVED		Reserved.	0x0	R

OFFSET TRIM REGISTERS

Offset trim registers are each four bits and offer user set, offset adjustments in twos complement format. The scale factor of these registers is shown in Figure 36.

X-AXIS OFFSET TRIM REGISTER, LSB

Address: 0x20, Reset: 0x00, Name: OFFSET_X

Table 35. Bit Descriptions for OFFSET_X

Bits	Bit Name	Settings	Description	Reset	Access
[7:4]	RESERVED		Reserved.	0x0	R
[3:0]	OFFSET_X		Offset added to x-axis data.	0x0	R/W

Y-AXIS OFFSET TRIM REGISTER, LSB

Address: 0x21, Reset: 0x00, Name: OFFSET_Y

Table 36. Bit Descriptions for OFFSET_Y

Bits	Bit Name	Settings	Description	Reset	Access
[7:4]	RESERVED		Reserved.	0x0	R
[3:0]	OFFSET_Y		Offset added to y-axis data.	0x0	R/W

Z-AXIS OFFSET TRIM REGISTER, LSB

Address: 0x22, Reset: 0x00, Name: OFFSET_Z

Table 37. Bit Descriptions for OFFSET_Z

Bits	Bit Name	Settings	Description	Reset	Access
[7:4]	RESERVED		Reserved.	0x0	R
[3:0]	OFFSET_Z		Offset added to z-axis data.	0x0	R/W

X-AXIS ACTIVITY THRESHOLD REGISTER, MSB

Address: 0x23, Reset: 0x00, Name: THRESH_ACT_X_H

This 11-bit unsigned value sets the threshold for activity detection. This value is set in codes and the scale factor is 100 mg/code. To detect activity, the absolute value of the 12-bit acceleration data is compared with the 11-bit (unsigned) activity threshold value. The THRESH_ACT_x_L register contains the least significant bits and the THRESH_ACT_x_H register contains the most significant byte of the activity threshold value.

Table 38. Bit Descriptions for THRESH_ACT_X_H

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	THRESH_ACT_X[10:3]		Threshold for activity detection. The 8 MSBs of x-axis threshold.	0x0	R/W

ACTIVITY TIME REGISTER**Address: 0x29, Reset: 0x00, Name: TIME_ACT**

The activity timer implements a robust activity detection that minimizes false positive motion triggers. When the timer is used, only sustained motion can trigger activity detection. The time (in milliseconds) is given by the following equation:

$$Time = TIME_ACT \times 3.3 \text{ ms per code}$$

where:

TIME_ACT is the value set in this register.

3.3 ms per code is the scale factor of the *TIME_ACT* register for ODR = 6400 Hz. It is 6.6 ms per code for ODR = 3200 Hz and below. See the Activity Timer section for more information.

**Table 44. Bit Descriptions for TIME_ACT**

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	ACT_COUNT		Number of multiples of 3.3 ms activity timer for which above threshold acceleration is required to detect activity. It is 3.3 ms per code for 6400 Hz ODR, and it is 6.6 ms per code for 3200 Hz ODR and below.	0x0	R/W

X-AXIS INACTIVITY THRESHOLD REGISTER, MSB**Address: 0x2A, Reset: 0x00, Name: THRESH_INACT_X_H**

This 11-bit unsigned value sets the threshold for inactivity detection. This value is set in codes and the scale factor is 100 mg/code. To detect inactivity, the absolute value of the 12-bit acceleration data is compared with the 11-bit (unsigned) inactivity threshold value. The *THRESH_INACT_x_L* register contains the least significant bits and the *THRESH_INACT_x_H* register contains the most significant byte of the inactivity threshold value.

INACTIVITY TIME REGISTERS

The 16-bit value in these registers sets the time that all enabled axes must be lower than the inactivity threshold for an inactivity event to be detected. The TIME_INACT_L register holds the eight LSBs, and the TIME_INACT_H register holds the eight MSBs of the 16-bit TIME_INACT value.

Calculate the time as follows:

$$Time = TIME_INACT \times 26 \text{ ms per code}$$

where:

TIME_INACT is the 16-bit value set by the TIME_INACT_L register (eight LSBs) and the TIME_INACT_H register (eight MSBs).

26 ms per code is the scale factor of the TIME_INACT_L and TIME_INACT_H registers for 3200 Hz and below. It is 13 ms per code of ODR = 6400 Hz. See the Inactivity Timer section for more information.

INACTIVITY TIMER REGISTER, MSB

Address: 0x30, Reset: 0x00, Name: TIME_INACT_H

[7:0] INACT_COUNT[15:8] (R/W)
 Number of multiples of 26 ms inactivity timer for which below threshold required to detect inactivity.

Table 51. Bit Descriptions for TIME_INACT_H

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	INACT_COUNT[15:8]		Number of multiples of 26 ms inactivity timer for which below threshold acceleration is required to detect inactivity. It is 26 ms per code for 3200 Hz ODR and below, and it is 13 ms per code for 6400 Hz ODR.	0x0	R/W

INACTIVITY TIMER REGISTER, LSB

Address: 0x31, Reset: 0x00, Name: TIME_INACT_L

[7:0] INACT_COUNT[7:0] (R/W)
 Number of multiples of 26 ms inactivity timer for which below threshold required to detect inactivity.

Table 52. Bit Descriptions for TIME_INACT_L

[7:0]	INACT_COUNT[7:0]		Number of multiples of 26 ms inactivity timer for which below threshold acceleration is required to detect inactivity.	0x0	R/W

X-AXIS MOTION WARNING THRESHOLD REGISTER, MSB

Address: 0x32, Reset: 0x00, Name: THRESH_ACT2_X_H

This 11-bit unsigned value sets the threshold for motion detection. This value is set in codes and the scale factor is 100 mg/code. To detect motion, the absolute value of the 12-bit acceleration data is compared with the 11-bit (unsigned) ACTIVITY2 threshold value. The THRESH_ACT2_x_L register contains the least significant bits and the THRESH_ACT2_x_H register contains the most significant byte of the ACTIVITY2 threshold value.

Table 53. Bit Descriptions for THRESH_ACT2_X_H

FIFO SAMPLES REGISTER

Address: 0x39, Reset: 0x80, Name: FIFO_SAMPLES

Use the FIFO_SAMPLES value to specify the number of samples to store in the FIFO. The 8 least significant bits (LSBs) of the FIFO_SAMPLES value are stored in this register. The most significant bit (MSB) of the FIFO_SAMPLES value is Bit 0 of the FIFO_CTL register.

The default value of this register is 0x80 to avoid triggering the FIFO watermark interrupt (see the FIFO Watermark section for more information). In trigger FIFO mode, FIFO_SAMPLES program the number of samples to be saved after the trigger is detected.

Table 60. Bit Descriptions for FIFO_SAMPLES

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	FIFO_SAMPLES[7:0]		FIFO Samples. Watermark number of FIFO samples that triggers a FIFO_FULL condition when reached. Values range from 0 to 512.	0x80	R/W

FIFO CONTROL REGISTER

Address: 0x3A, Reset: 0x00, Name: FIFO_CTL

Use this register to specify the operating parameters for the FIFO.

Table 61. Bit Descriptions for FIFO_CTL

Bits	Bit Name	Settings	Description	Reset	Access
[7:6]	RESERVED		Reserved.	0x0	R
[5:3]	FIFO_FORMAT	111 001 010 011 100 101 110 000	FIFO Format. Specifies which data is stored in the FIFO buffer. FIFO stores peak acceleration (x, y, and z) of every over threshold event. FIFO stores x-axis acceleration data only. FIFO stores y-axis acceleration data only. FIFO stores x- and y-axis acceleration data. FIFO stores z-axis acceleration data only. FIFO stores x- and z-axis acceleration data. FIFO stores y- and z-axis acceleration data. FIFO stores x-, y- and z-axis acceleration data.	0x0	R/W

Bits	Bit Name	Settings	Description	Reset	Access
[2:1]	FIFO_MODE	0 FIFO is bypassed. 1 FIFO operates in stream mode. 10 FIFO operates in trigger mode. 11 FIFO operates in oldest saved mode.	FIFO Mode. Specifies FIFO operating mode.	0x0	R/W
0	FIFO_SAMPLES[8]		FIFO Samples. Watermark number of FIFO samples that triggers a FIFO_FULL condition when reached. Values range from 0 to 512.	0x0	R/W

INTERRUPT PIN FUNCTION MAP REGISTERS

Address: 0x3B, Reset: 0x00, Name: INT1_MAP

The INT1_MAP and INT2_MAP registers configure the INT1 and INT2 interrupt pins, respectively. Bits[6:0] select which function(s) generate an interrupt on the pin. If its corresponding bit is set to 1, the function generates an interrupt on the INTx pin. Bit B7 configures whether the pin operates in active high (B7 low) or active low (B7 high) mode. Any number of functions can be selected simultaneously for each pin. If multiple functions are selected, their conditions are OR'ed together to determine the INTx pin state. The status of each function can be determined by reading the status register. If no interrupts are mapped to an INTx pin, the pin remains in a high impedance state.

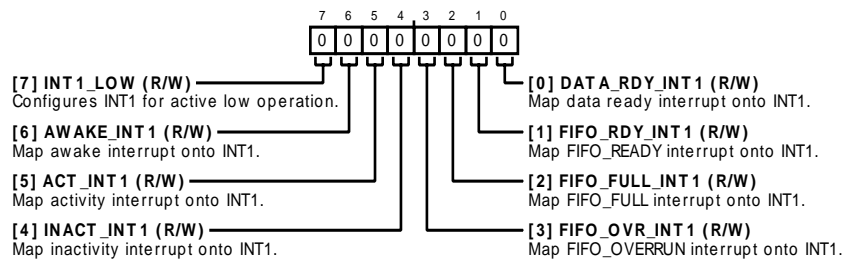

Table 62. Bit Descriptions for INT1_MAP

Bits	Bit Name	Settings	Description	Reset	Access
7	INT1_LOW		Configures INT1 for active low operation.	0x0	R/W
6	AWAKE_INT1		Map awake interrupt onto INT1.	0x0	R/W
5	ACT_INT1		Map activity interrupt onto INT1.	0x0	R/W
4	INACT_INT1		Map inactivity interrupt onto INT1.	0x0	R/W
3	FIFO_OVR_INT1		Map FIFO_OVERRUN interrupt onto INT1.	0x0	R/W
2	FIFO_FULL_INT1		Map FIFO_FULL interrupt onto INT1.	0x0	R/W
1	FIFO_RDY_INT1		Map FIFO_READY interrupt onto INT1.	0x0	R/W
0	DATA_RDY_INT1		Map data ready interrupt onto INT1.	0x0	R/W

INT2 FUNCTION MAP REGISTER

Address: 0x3C, Reset: 0x00, Name: INT2_MAP

Table 63. Bit Descriptions for INT2_MAP

Bits	Bit Name	Settings	Description	Reset	Access
7	INT2_LOW		Configures INT2 for active low operation.	0x0	R/W
6	AWAKE_INT2		Map awake interrupt onto INT2.	0x0	R/W
5	ACT2_INT2		Map Activity 2 (motion warning) interrupt onto INT2.	0x0	R/W
4	INACT_INT2		Map inactivity interrupt onto INT2.	0x0	R/W
3	FIFO_OVR_INT2		Map FIFO_OVERRUN interrupt onto INT2.	0x0	R/W
2	FIFO_FULL_INT2		Map FIFO_FULL interrupt onto INT2.	0x0	R/W
1	FIFO_RDY_INT2		Map FIFO_READY interrupt onto INT2.	0x0	R/W
0	DATA_RDY_INT2		Map data ready interrupt onto INT2.	0x0	R/W

EXTERNAL TIMING CONTROL REGISTER

Address: 0x3D, Reset: 0x00, Name: TIMING

Use this register to control the ADXL372 timing parameters: ODR and external timing triggers.

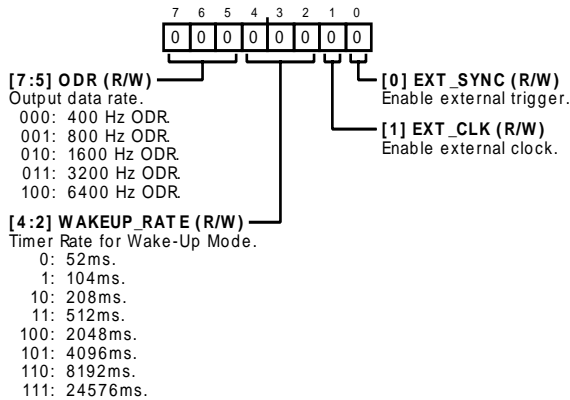

Table 64. Bit Descriptions for TIMING

Bits	Bit Name	Settings	Description	Reset	Access
[7:5]	ODR		Output data rate.	0x0	R/W
		000	400 Hz ODR.		
		001	800 Hz ODR.		
		010	1600 Hz ODR.		
		011	3200 Hz ODR.		
		100	6400 Hz ODR.		

Bits	Bit Name	Settings	Description	Reset	Access
[4:2]	WAKEUP_RATE	0 52 ms. 1 104 ms. 10 208 ms. 11 512 ms. 100 2048 ms. 101 4096 ms. 110 8192 ms. 111 24576 ms.	Timer Rate for Wake-Up Mode.	0x0	R/W
1	EXT_CLK		Enable external clock.	0x0	R/W
0	EXT_SYNC		Enable external trigger.	0x0	R/W

MEASUREMENT CONTROL REGISTER

Address: 0x3E, Reset: 0x00, Name: MEASURE

Use this register to control several measurement settings.

Table 65. Bit Descriptions for MEASURE

Bits	Bit Name	Settings	Description	Reset	Access
7	USER_OR_DISABLE		User overrange disable.	0x0	R/W
6	AUTOSLEEP		Autosleep. When set to 1, autosleep is enabled, and the device enters wake-up mode automatically upon detection of inactivity. Activity and inactivity detection must be in linked mode or loop mode (the LINKLOOP bits in the MEASURE register) to enable autosleep; otherwise, the bit is ignored.	0x0	R/W
[5:4]	LINKLOOP	0 Default Mode. Activity and inactivity detection, when enabled, operate simultaneously and their interrupts (if mapped) must be acknowledged by the host processor by reading the status register. Autosleep is disabled in this mode. 1 Linked Mode. Activity and inactivity detection are linked sequentially such that only one is enabled at a time. Their interrupts (if mapped) must be acknowledged by the host processor by reading the status register. 10 Looped Mode. Activity and inactivity detection are linked sequentially such that only one is enabled at a time, and their interrupts are internally acknowledged (do not need to be serviced by the host processor). To use either linked or looped mode, both ACT_x_EN and INACT_x_EN must be set to 1; otherwise, the default mode is used. For additional information, refer to the Linking Activity and Inactivity Detection section.	Link/Loop Activity Processing. These bits select how activity and inactivity processing are linked.	0x0	R/W

Bits	Bit Name	Settings	Description	Reset	Access
3	LOW_NOISE	0 1	Low Noise. Selects low noise operation. Normal operation. Device operates at the normal noise level and ultralow current consumption Low noise operation. Device operates at ~1/3 the normal noise level.	0x0	R/W
[2:0]	BANDWIDTH	000 001 010 011 100	Bandwidth. Select the desired output signal bandwidth. A 4-pole low-pass filter at the selected frequency limits the signal bandwidth. 200 Hz Bandwidth. 400 Hz Bandwidth. 800 Hz Bandwidth. 1600 Hz Bandwidth. 3200 Hz Bandwidth.	0x0	R/W

POWER CONTROL REGISTER

Address: 0x3F, Reset: 0x00, Name: POWER_CTL

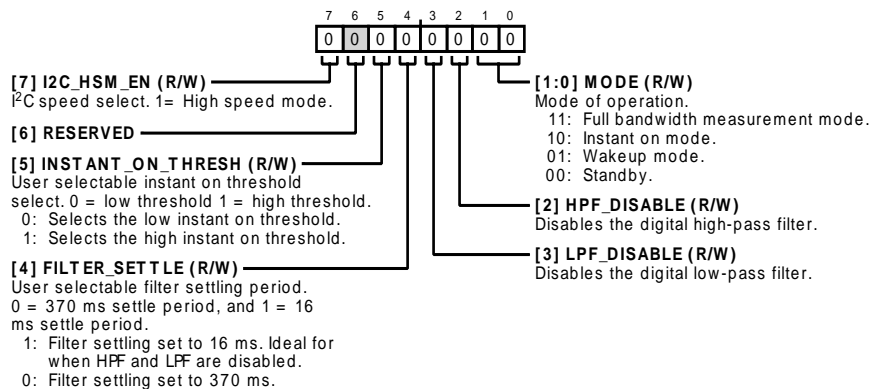

Table 66. Bit Descriptions for POWER_CTL

Bits	Bit Name	Settings	Description	Reset	Access
7	I2C_HSM_EN		I ² C speed select. 1 = high speed mode.	0x0	R/W
6	RESERVED		Reserved.	0x0	R
5	INSTANT_ON_THRESH	0 1	User selectable instant on threshold select. 0 = low threshold, 1 = high threshold. Selects the low instant on threshold. Selects the high instant on threshold.	0x0	R/W
4	FILTER_SETTLE	0 1	User selectable filter settling period. 0 = 370 ms settle period, and 1 = 16 ms settle period. Filter settling set to 370 ms. Filter settling set to 16 ms. Ideal for when HPF and LPF are disabled.	0x0	R/W
3	LPF_DISABLE		Disables the digital low-pass filter.	0x0	R/W
2	HPF_DISABLE		Disables the digital high-pass filter.	0x0	R/W
[1:0]	MODE	11 10 01 00	Mode of operation. Full bandwidth measurement mode. Instant on mode. Wake up mode. Standby.	0x0	R/W

SELF TEST REGISTER

Address: 0x40, Reset: 0x00, Name: SELF_TEST

Refer to the Self Test section for information on the operation of the self test feature, and see the Self Test Procedure section for guidelines on how to use this functionality.

Table 67. Bit Descriptions for SELF_TEST

Bits	Bit Name	Settings	Description	Reset	Access
[7:3]	RESERVED		Reserved.	0x0	R
2	USER_ST		User self test pass if = 1.	0x0	R
1	ST_DONE		Self test finished.	0x0	R
0	ST		Self test. Writing a 1 to this bit initiates self test. Writing a 0 clears self test.	0x0	R/W1

RESET (CLEARS) REGISTER, PART IN STANDBY MODE

Address: 0x41, Reset: 0x00, Name: RESET

Table 68. Bit Descriptions for RESET

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	Reset		Writing code 0x52 resets the device.	0x0	W

FIFO ACCESS REGISTER

Address: 0x42, Reset: 0x00, Name: FIFO_DATA

Read this register to access data stored in the FIFO.

Table 69. Bit Descriptions for FIFO_DATA

Bits	Bit Name	Settings	Description	Reset	Access
[7:0]	FIFO_DATA		FIFO Data. A read to this address pops a 2-byte word of axis data from the FIFO. FIFO data is formatted to 2 bytes (16 bits), most significant byte first. Two subsequent reads complete the transaction of this data onto the interface. Continued reading of this field continues to pop the FIFO every third read. Multibyte reads to this address do not increment the address pointer. If this address is read due to an auto-increment from the previous address, it does not pop the FIFO. It returns zeros and increment on to the next address.	0x0	R

APPLICATIONS INFORMATION

APPLICATION EXAMPLES

This section includes a few application circuits, highlighting useful features of the [ADXL372](#).

Power Supply Decoupling

Figure 48 shows the recommended bypass capacitors for use with the [ADXL372](#).

Figure 48. Recommended Bypass Capacitors

A 0.1 μF ceramic capacitor (C_S) at V_S and a 0.1 μF ceramic capacitor (C_{IO}) at $V_{DD I/O}$ placed as close as possible to the [ADXL372](#) supply pins are recommended to adequately decouple the accelerometer from noise on the power supply. It is recommended that V_S and $V_{DD I/O}$ be separate supplies to minimize digital clocking noise on the V_S supply. If this is not possible, additional filtering of the supplies may be necessary.

If additional decoupling is necessary, a resistor or ferrite bead, no larger than 100 Ω , in series with V_S , is recommended. Additionally, increasing the bypass capacitance on V_S to a 1 μF tantalum capacitor in parallel with a 0.1 μF ceramic capacitor may also improve noise.

Ensure that the connection from the [ADXL372](#) ground to the power supply ground has low impedance because noise transmitted through ground has an effect similar to noise transmitted through V_S .

Using External Timing Triggers

Figure 49 shows an application diagram for using the INT1 pin as the input for an external clock. In this mode, the external clock determines all accelerometer timing, including the output data rate and bandwidth.

Set the EXT_CLK bit in the TIMING register to enable this feature.

Figure 49. INT1 Pin as Input for External Clock

Figure 50 is an application diagram for using the INT2 pin as a trigger for synchronized sampling. Acceleration samples are produced every time this trigger is activated. Set the EXT_SYNC bit in the TIMING register to enable this feature.

Figure 50. Using the INT2 Pin to Trigger Synchronized Sampling

OPERATION AT VOLTAGES OTHER THAN 2.5 V

The [ADXL372](#) is tested and specified at a supply voltage of $V_S = 2.5 \text{ V}$; however, it can be powered with a V_S as high as 3.5 V or as low as 1.6 V. Some performance parameters change as the supply voltage changes, including the supply current, noise, offset, and sensitivity.

OPERATION AT TEMPERATURES OTHER THAN AMBIENT

The [ADXL372](#) is tested and specified at an ambient temperature; however, it is rated for temperatures between -40°C and $+105^\circ\text{C}$. Some performance parameters change along with temperature, such as offset, sensitivity, clock performance, and current. Some of these temperature variations are characterized in Table 1, and others are shown in the figures within the Typical Performance Characteristics section.

MECHANICAL CONSIDERATIONS FOR MOUNTING

Mount the [ADXL372](#) on the PCB in a location close to a hard mounting point of the PCB to the case. Mounting the [ADXL372](#) at an unsupported PCB location, as shown in Figure 51, can result in large, apparent measurement errors due to undamped PCB vibration. Locating the accelerometer near a hard mounting point ensures that any PCB vibration at the accelerometer is above the mechanical sensor resonant frequency of the accelerometer and, therefore, effectively invisible to the accelerometer. Multiple mounting points, close to the sensor, and/or a thicker PCB also help to reduce the effect of system resonance on the performance of the sensor.

ORDERING GUIDE

Model ¹	Temperature Range	Package Description	Package Option	Quantity
ADXL372BCCZ-RL	-40°C to +105°C	16-Terminal Land Grid Array [LGA]	CC-16-4	5,000
ADXL372BCCZ-RL7	-40°C to +105°C	16-Terminal Land Grid Array [LGA]	CC-16-4	1,500
EVAL-ADXL372Z	-40°C to +105°C	Breakout Board		

¹ Z = RoHS Compliant Part.
