

## FEATURES

- Charges Any Size Capacitor
- Easily Adjustable Output Voltage
- Drives High Current NMOS FETs
- Primary-Side Sense—No Output Voltage Divider Necessary
- Wide Input Range: 3V to 24V
- Drives Gate to  $V_{CC} - 2V$
- Available in 10-Lead MS Package

## APPLICATIONS

- Emergency Warning Beacons
- Professional Photoflash Systems
- Security/Inventory Control Systems
- High Voltage Power Supply
- Electric Fences
- Detonators

## DESCRIPTION

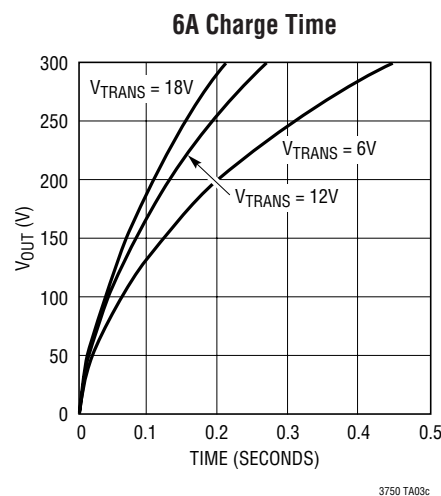

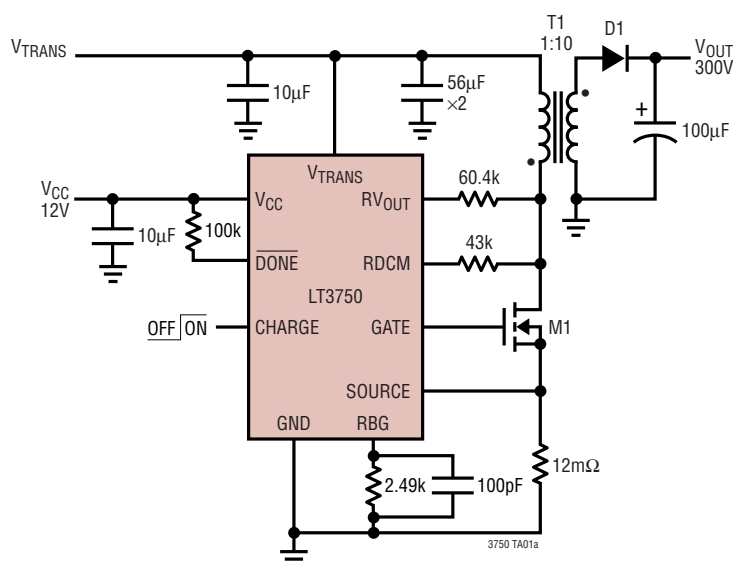

The LT<sup>®</sup>3750 is a flyback converter designed to rapidly charge large capacitors to a user-adjustable target voltage. A patented boundary mode control scheme\* minimizes transition losses and reduces transformer size. The transformer turns ratio and two external resistors easily adjust the output voltage.\* A low 78mV current sense accurately limits peak switch current and also helps to maximize efficiency. With a wide input voltage range, the LT3750 can operate from a variety of power sources. A typical application can charge a 100 $\mu$ F capacitor to 300V in less than 300ms.

The CHARGE pin gives full control of the LT3750 to the user. The DONE pin indicates when the capacitor has reached its programmed value and the part has stopped charging.

LT, LTC and LT are registered trademarks of Linear Technology Corporation. All other trademarks are the property of their respective owners. \*Protected by U.S. Patents, including 6518733, 6636021.

## TYPICAL APPLICATION

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** The LT3750E is guaranteed to meet performance specifications from  $0^{\circ}\text{C}$  to  $70^{\circ}\text{C}$ . Specifications over the  $-40^{\circ}\text{C}$  to  $85^{\circ}\text{C}$  operating temperature range are assured by design, characterization and correlation with statistical process controls.

**Note 3:** Refer to Block Diagram for  $V_{DRAIN}$  definition.

## PIN FUNCTIONS

**V<sub>TRANS</sub> (Pin 1):** Transformer Supply Pin. Powers the primary coil of the transformer as well as internal circuitry that performs boundary mode detection. Bypass at the pin with a 1 $\mu$ F to 10 $\mu$ F capacitor. Bypass the primary winding of the transformer with a large capacitor.

**$\overline{\text{DONE}}$  (Pin 2):** Open Collector Indication Pin. When target output voltage is reached, an NPN transistor turns on. Requires a pull-up resistor or current source. Any fault conditions such as thermal shutdown or undervoltage lockout will also turn on the NPN.

**CHARGE (Pin 3):** Charge Pin. Initiates a new charge cycle when brought high or discontinues charging and puts part into shutdown when low. To properly enable the device, a step input with a minimum ramp rate of 1V/ $\mu$ s is required. Drive to 1.1V or higher to enable the device; drive below 0.2V to disable the device.

**V<sub>CC</sub> (Pin 4):** Input Supply Pin. Bypass locally with a ceramic capacitor. A 1 $\mu$ F to 10 $\mu$ F ceramic capacitor should be sufficient for most applications.

**GND (Pin 5):** Ground Pin. Connect directly to local ground plane.

**SOURCE (Pin 6):** Source Pin. Senses NMOS drain current. Connect NMOS source terminal and current sense resistor to this pin. The current limit is 78mV/R<sub>SENSE</sub>.

**GATE (Pin 7):** Gate Pin. Connect NMOS gate terminal to this pin. Internal gate driver will drive voltage to within V<sub>CC</sub> – 2V during each switching cycle.

**RDCM (Pin 8):** Discontinuous Mode Sense Pin. Senses when current in transformer has decayed to zero and initiates a new charge cycle if output voltage target has not been reached. Place a resistor between this pin and the drain of the NMOS. A good choice is a 43k, 5% resistor.

**RV<sub>OUT</sub> (Pin 9):** Output Voltage VI Converter Pin. Develops a current proportional to output capacitor voltage. Connect a resistor between this pin and the drain of the NMOS.

**RBG (Pin 10):** Output Voltage Sense Pin. Senses the voltage across the RBG resistor, which is proportional to the current flowing into the RV<sub>OUT</sub> pin. When voltage equals 1.24V, charging is disabled and  $\overline{\text{DONE}}$  pin goes low. Connect a resistor (2.5k or less is recommended) from this pin to GND. A 2.49k, 1% resistor is a good choice.

**BLOCK DIAGRAM**

# OPERATION

The LT3750 is designed to charge capacitors quickly and efficiently. Operation can be best understood by referring to Figures 1 and 2. Operation proceeds in four phases: 1. Start-up, 2. Primary-side charging, 3. Secondary energy transfer, 4. Discontinuous mode sensing.

## 1. Start-Up

Start-up occurs for approximately 20μs after the charge pin is raised high. During this phase, a one-shot enables the master latch and turns on the NMOS. The master latch will remain in the set state until the target output voltage is reached or a fault condition resets it.

(1a) Equivalent Circuit During Primary-Side Charging

(1b) Equivalent Circuit During Secondary Energy Transfer and Output Detection

(1c) Equivalent Circuit During Discontinuous Mode Detection

Figure 1. Equivalent Circuits

## 2. Primary Side Charging

When the NMOS on latch is set, the gate driver rapidly charges the gate pin to  $V_{CC} - 2V$ . The external NMOS turns on forcing  $V_{TRANS} - V_{DS(ON)}$  across the primary winding. Consequently, current in the primary coil rises linearly at

Figure 2. Idealized Charging Waveforms

## OPERATION

a rate  $(V_{\text{TRANS}} - V_{\text{DS(ON)}})/L_{\text{PRI}}$ . The input voltage is mirrored on the secondary winding  $-N \cdot (V_{\text{TRANS}} - V_{\text{DS(ON)}})$  which reverse biases the diode and prevents current flow in the secondary winding. Thus, energy is stored in the core of the transformer.

### 3. Secondary Energy Transfer

When current limit is reached, the current limit comparator resets the NMOS on-latch and the device enters the third phase of operation, secondary energy transfer. The energy stored in the transformer core forward biases the diode and current flows into the output capacitor. During this time, the output voltage (neglecting the diode drop) is reflected back to the primary coil. If the target output

voltage is reached, the  $V_{\text{OUT}}$  comparator resets the master latch and the DONE pin goes low. Otherwise, the device enters the next phase of operation.

### 4. Discontinuous Mode Detection

Once all the current is transferred to the output capacitor,  $(V_{\text{OUT}} + V_{\text{DIODE}})/N$  will appear across the primary winding. A transformer with no energy cannot support a DC voltage, so, the voltage across the primary will decay to zero. In other words, the drain of the NMOS will ring down from  $V_{\text{TRANS}} + (V_{\text{OUT}} + V_{\text{DIODE}})/N$  to  $V_{\text{TRANS}}$ . When the drain voltage falls to  $V_{\text{TRANS}} + 36\text{mV}$ , the DCM comparator sets the NMOS on-latch and a new charge cycle begins. Steps 2-4 continue until the target output voltage is reached.

## APPLICATIONS INFORMATION

### Safety Warning

Large capacitors charged to high voltage can deliver a lethal amount of energy if handled improperly. It is particularly important to observe appropriate safety measures when designing the LT3750 into applications. First, create a discharge circuit that allows the designer to safely discharge the output capacitor. Second, adequately space high voltage nodes from adjacent traces to satisfy printed circuit board voltage breakdown requirements. High voltage nodes are the drain of the NMOS, the secondary side of the transformer, and the output.

### Transformer Selection

The flyback transformer is critical to proper operation of the LT3750. It must be designed carefully so that it does not cause excessive current or voltage on any pin of the part.

As with all circuits, the LT3750 has finite bandwidth. In order to give the LT3750 sufficient time to detect the output voltage, observe the following restrictions on the primary inductance:

$$L_{PRI} \geq \frac{V_{OUT} \cdot 1\mu s}{N \cdot I_{PK}}$$

otherwise, the LT3750 may overcharge the output.

Linear Technology has worked with several leading magnetic component manufacturers to produce flyback transformers for use with the LT3750. Table 1 summarizes the particular transformer characteristics.

	DA2034-AL	20.6 × 30 × 11.3	10	10	1:10

### Switching Period

The LT3750 employs an open-loop control scheme causing the switching period to decrease with output voltage. Typical switching frequency is between 100kHz to 300kHz. Figure 3 shows typical switching period in an application with a 3A peak current.

**Figure 3. Typical Switching Period vs V<sub>OUT</sub>**

### Output Diode Selection

When choosing the rectifying diode, ensure its peak repetitive forward current rating exceeds the peak current ( $I_{PK}/N$ ) and that the peak repetitive reverse voltage rating exceeds  $V_{OUT} + (N)(V_{TRANS})$ . The average current through the diode varies during the charge cycle because the switching period decreases as  $V_{OUT}$  increases. The average current through the diode is greatest when the

## APPLICATIONS INFORMATION

output capacitor is almost completely charged and is given by:

$$I_{AVG,D} = \frac{I_{PK} \cdot V_{TRANS}}{2(V_{OUT(PK)} + N \cdot V_{TRANS})}$$

The output diode's continuous forward current rating must exceed  $I_{AVG,D}$ .

At a minimum, the diode must satisfy all the previously mentioned specifications to guarantee proper operation. However, to optimize charge time, reverse recovery time and reverse bias leakage current should be considered. Excessive diode reverse recovery times can cause appreciable discharging of the output capacitor thereby increasing charge time. Choose a diode with a reverse recovery time of less than 100ns. Diode leakage current under high reverse bias bleeds the output capacitor of charge, also increasing charge time. Choose a diode that has minimal reverse bias leakage current. Table 2 recommends several output diodes for various output voltages with adequate reverse recovery time.

**Table 2. Recommended Output Diodes**

MANUFACTURER	PART NUMBER	I <sub>DC</sub> (A)	PEAK REPETITIVE REVERSE VOLTAGE (V)	PACKAGE

	BYD167	1	500	SOD87

### Bypass Capacitor Selection

Use a high quality X5R or X7R dielectric ceramic capacitor placed close to the LT3750 to locally bypass the  $V_{CC}$  and  $V_{TRANS}$  pins. For most applications, a 1 $\mu$ F to 10 $\mu$ F ceramic capacitor should suffice for  $V_{CC}$  and a 1 $\mu$ F to 10 $\mu$ F for the  $V_{TRANS}$  pin.

The high peak currents flowing through the transformer necessitate a larger ( $\gg 10\mu$ F) capacitor to bypass the primary winding of the transformer. Inadequate bypassing

can result in improper operation. This most often manifests itself in two ways. The first is when the primary winding current looks distorted instead of triangular. This substantially reduces the efficiency and increases the charge time. The second way is when the LT3750 fails to detect discontinuous mode after the first switching cycle. Both of these problems are solved by increasing the amount of capacitive bypassing for the transformer. Choose capacitors that can handle the high RMS ripple currents common in flyback regulators.

### Output Capacitor Selection

For photoflash applications, the output capacitor will be discharged into a Xenon flash bulb. Only a pulse capacitor or photoflash capacitor is able to survive such a harsh event. Igniting a typical Xenon bulb requires approximately 250V to 350V stored on a capacitor on the order of hundreds of microfarads.

### NMOS Selection

Choose an external NMOS with minimal gate charge and on resistance that satisfies current limit and voltage breakdown requirements. The gate is nominally driven to  $V_{CC} - 2V$  during each charge cycle. Ensure that this does not exceed the maximum gate to source voltage rating of the NMOS but enhances the channel enough to minimize the on resistance. Similarly, the maximum drain-source voltage rating of the NMOS must exceed  $V_{TRANS} + V_{OUT}/N$  or the magnitude of the leakage inductance spike, whichever is greater. The maximum instantaneous drain current must exceed current limit. Because the switching period decreases with output voltage, the average current through the NMOS is greatest when the output is nearly charged and is given by:

$$I_{AVG,M} = \frac{I_{PK} \cdot V_{OUT(PK)}}{2(V_{OUT(PK)} + N \cdot V_{TRANS})}$$

## APPLICATIONS INFORMATION

**Table 4. Recommended NMOS Transistors**

MANUFACTURER	PART NUMBER	I <sub>D</sub> (A)	V <sub>DS(MAX)</sub> (V)	V <sub>GS(MAX)</sub> (V)	R <sub>DS(ON)</sub> (mΩ)	PACKAGE
Philips Semiconductor (www.semiconductors.philips.com)	PHM21NQ15T	22.2	150	20	55	HVSON8
	PHK12NQ10T	11.6	100	20	28	SO-8
	PHT6NQ10Y	6.5	100	20	90	SOT223

International Rectifier (www.irf.com)	IRF7488	6.3	80	20	29	SO-8
	IRF7493	9.3	80	20	15	SO-8
	IRF6644	10.3	100	20	10.7	DirectFET

The transistor’s continuous drain current rating must exceed I<sub>AVG,M</sub>.

Table 4 lists recommended NMOS transistors.

### Setting Current Limit

A sense resistor from the SOURCE pin to GND implements current limit. The current limit is nominally 78mV/R<sub>SENSE</sub>. The average power dissipation rating of the current sense resistor must exceed:

$$P_{RESISTOR} \geq \frac{I_{PK}^2 \cdot R_{SENSE}}{3} \left( \frac{V_{OUT(PK)}}{V_{OUT(PK)} + N \cdot V_{TRANS}} \right)$$

Additionally, there is approximately a 100ns propagation delay from the time that peak current limit is detected to when the gate transitions to the low state. This delay increases the peak current limit by (V<sub>TRANS</sub>)(t<sub>DELAY</sub>)/L<sub>PRI</sub>.

### Setting The Target Output Voltage

The parameters that determine the target output voltage are the resistors R<sub>VOUT</sub> and R<sub>BG</sub>, the turns ratio of the transformer (N), and the voltage drop across the output diode (V<sub>DIODE</sub>). The target output voltage is set according to the following equation:

$$V_{OUT} = \left( 1.24V \cdot \frac{R_{VOUT}}{R_{BG}} \cdot N \right) - V_{DIODE}$$

Use at least 1% tolerance resistors for R<sub>VOUT</sub> and R<sub>BG</sub>. Choosing large value resistors for R<sub>BG</sub> decreases the amount of current that charges the parasitic internal capacitances and degrades the response time of the V<sub>OUT</sub> comparator. This may result in overcharging of the output capacitor. The maximum recommended value for R<sub>BG</sub> is 2.5k for typical applications.

When high primary currents are used, a voltage spike can prematurely trip the output voltage comparator. A 33pF to 100pF capacitor in parallel with R<sub>BG</sub> is sufficient to filter this spike for most applications. Always check that the voltage waveform on RBG does not overshoot and that it reaches a plateau at maximum V<sub>OUT</sub>.

### Discontinuous Mode Detection

The R<sub>DCM</sub> resistor stands off voltage transients on the drain node. A 43k, 5% resistor is recommended for 300V applications. Higher output voltages will require a larger resistor.

In order for the LT3750 to properly detect discontinuous mode and start a new charge cycle, the reflected voltage to the primary winding must exceed the discontinuous mode comparator threshold which is nominally 36mV. The worst-case condition occurs when V<sub>OUT</sub> is shorted to ground. When this occurs, the reflected voltage is simply the diode forward voltage drop divided by N.

## APPLICATIONS INFORMATION

### Board Layout

The high voltage operation of the the LT3750 demands careful attention to board layout. Observe the following points:

1. Minimize the area of the high voltage end of the secondary winding.
2. Provide sufficient spacing for all high voltage nodes (NMOS drain,  $V_{OUT}$  and the secondary winding of the transformer) in order to meet breakdown voltage requirements.

3. Keep the electrical path formed by C1, the primary of T1 and drain of the NMOS as small as possible. Increasing the size of this path effectively increases the leakage inductance of T1 resulting in an overvoltage condition on the drain of the NMOS.
