

TOSHIBA CMOS Digital Integrated Circuit Silicon Monolithic

# TC74HC423AP, TC74HC423AF

## Dual Retriggerable Monostable Multivibrator

The TC74HC423A is a high speed CMOS MONOSTABLE MULTIVIBRATOR fabricated with silicon gate C<sup>2</sup>MOS technology.

It achieves the high speed operation similar to equivalent LSTTL while maintaining the CMOS low power dissipation.

There are two trigger inputs,  $\overline{A}$  input (negative edge), and B input (positive edge). These inputs are valid for a slow rise/fall time signal ( $t_r = t_f = 1$  s) as they are schmitt trigger inputs.

After triggering, the output stays in a MONOSTABLE state for a time period determined by the external resistor and capacitor ( $R_x, C_x$ ). A low level at the  $\overline{CLR}$  input breaks this state. In the MONOSTABLE state, if a new trigger is applied, it extends the MONOSTABLE period (retrigger mode).

Limitations for  $C_x$  and  $R_x$  are:

External capacitor,  $C_x$ : No limit

External resistor,  $R_x$ :  $V_{CC} = 2.0$  V more than 5 k $\Omega$

$V_{CC} \geq 3.0$  V more than 1 k $\Omega$

All inputs are equipped with protection circuits against static discharge or transient excess voltage.

### Features (Note)

- High speed:  $t_{pd} = 25$  ns (typ.) at  $V_{CC} = 5$  V
- Low power dissipation
  - Standby state:  $I_{CC} = 4$   $\mu$ A (max) at  $T_a = 25^\circ$ C
  - Active state:  $I_{CC} = 700$   $\mu$ A (max) at  $V_{CC} = 5$  V
- High noise immunity:  $V_{NIH} = V_{NIL} = 28\%$   $V_{CC}$  (min)
- Output drive capability: 10 LSTTL loads
- Symmetrical output impedance:  $|I_{OH}| = I_{OL} = 4$  mA (min)
- Balanced propagation delays:  $t_{pLH} \approx t_{pHL}$
- Wide operating voltage range:  $V_{CC} (opr) = 2\sim 6$  V
- Pin and function compatible with 74LS423

Note: In the case of using only one circuit,  $\overline{CLR}$  should be tied to GND,  $R_x/C_x \cdot C_x \cdot Q \cdot \overline{Q}$  should be tied to OPEN, the other inputs should be tied to  $V_{CC}$  or GND.

Weight	
DIP16-P-300-2.54A	: 1.00 g (typ.)
SOP16-P-300-1.27A	: 0.18 g (typ.)

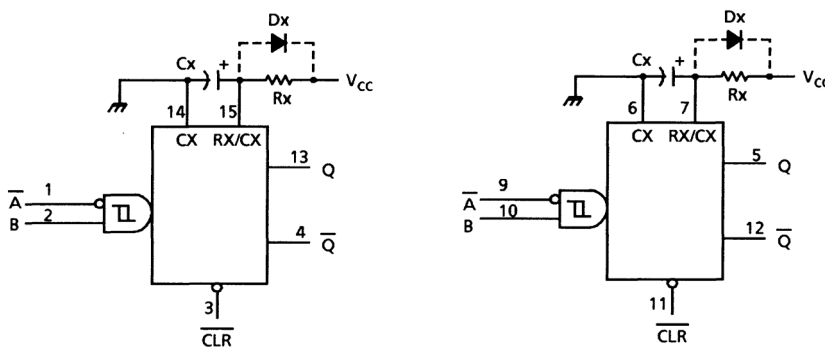

## Pin Assignment

## IEC Logic Symbol

## Block Diagram (Note 1)(Note 2)

Note 1: Cx, Rx, Dx are external capacitor, resistor, and diode, respectively.

Note 2: External clamping diode, Dx;

The external capacitor is charged to  $V_{CC}$  level in the wait state, i.e. when no trigger is applied.

If the supply voltage is turned off, Cx is discharged mainly through the internal (parasitic) diode. If Cx is sufficiently large and  $V_{CC}$  drops rapidly, there will be some possibility of damaging the IC through inrush current or latch-up. If the capacitance of the supply voltage filter is large enough and  $V_{CC}$  drops slowly, the inrush current is automatically limited and damage to the IC is avoided.

The maximum value of forward current through the parasitic diode is  $\pm 20$  mA.

In the case of a large Cx, the limit of fall time of the supply voltage is determined as follows:

$$t_f \geq (V_{CC} - 0.7) Cx / 20 \text{ mA}$$

( $t_f$  is the time between the supply voltage turn off and the supply voltage reaching  $0.4 V_{CC}$ .)

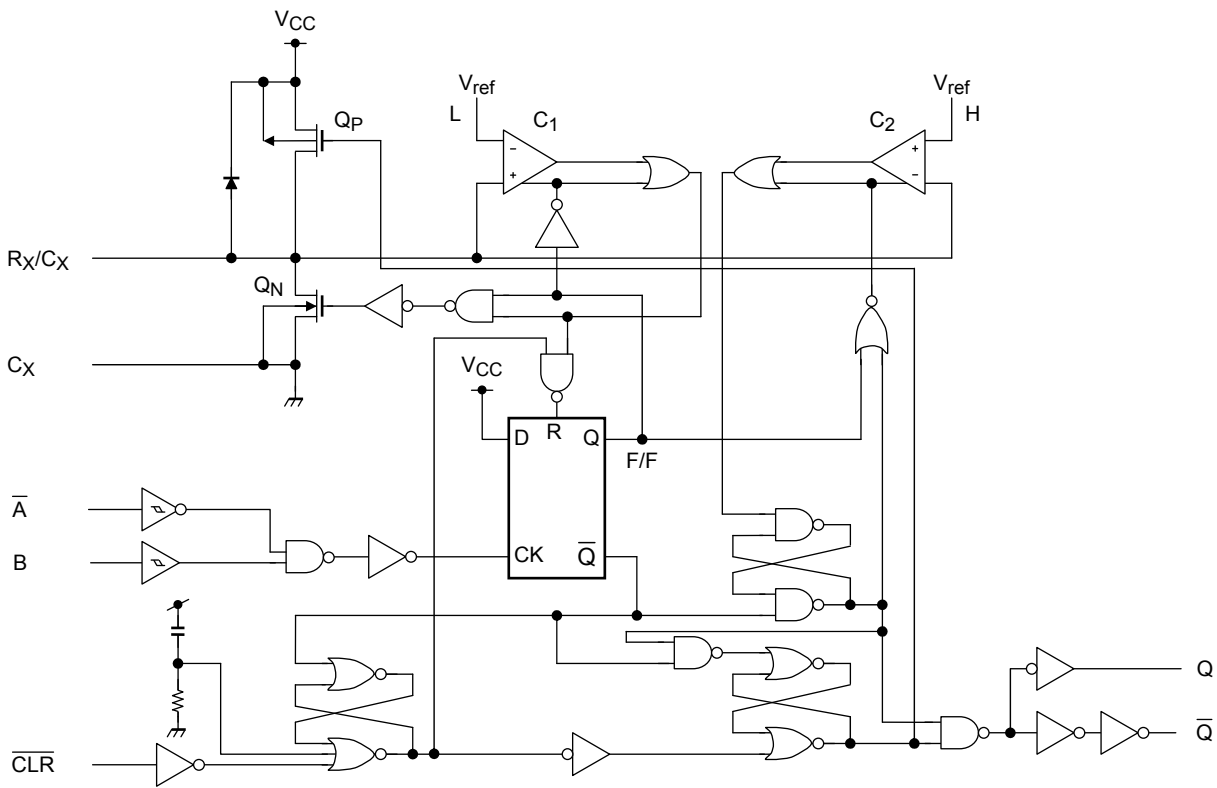

In the event a system does not satisfy the above condition, an external clamping diode (Dx) is needed to protect the IC from inrush current.

**Truth Table**

Inputs			Outputs		Note

H	X	H	L	H	Inhibit
L		H			Output Enable
X	X	L	L	H	Reset

X: Don't care

**System Diagram**

**Timing Chart**

**Functional Description**

(1) Stand-by state

The external capacitor C<sub>x</sub> is fully charged to V<sub>CC</sub> in the stand-by state. That means, before triggering, the Q<sub>P</sub> and Q<sub>N</sub> transistors which are connected to the Rx/C<sub>x</sub> node are in the off state. Two comparators that relate to the timing of the output pulse, and two reference voltage supplies turn off. The total supply current is only leakage current.

(2) Trigger operation

Trigger operation is effective in either of the following two cases. First, the condition where the  $\bar{A}$  input is low, and the B input has a rising signal; second, where the B input is high, and the  $\bar{A}$  input has a falling signal.

After a trigger becomes effective, comparators C1 and C2 start operating, and Q<sub>N</sub> is turned on. The external capacitor discharges through Q<sub>N</sub>. The voltage level of the Rx/C<sub>x</sub> node drops. If the Rx/C<sub>x</sub> voltage level falls to the internal reference voltage V<sub>ref L</sub>, the output of C1 becomes low. The flip-flop is then reset and Q<sub>N</sub> turns off. At that moment C1 stops but C2 continues operating.

After Q<sub>N</sub> turns off, the voltage at the Rx/C<sub>x</sub> starts rising at a rate determined by the time constant of external capacitor C<sub>x</sub> and resistor R<sub>x</sub>.

Upon the triggering, output Q becomes high, following some delay time of the internal F/F and gates. It stays high even if the voltage of Rx/C<sub>x</sub> changes from falling to rising. When Rx/C<sub>x</sub> reaches the internal reference voltage V<sub>ref H</sub>, the output of C2 becomes low, the output Q goes low and C2 stops its operation. That means, after triggering, when the voltage level of the Rx/C<sub>x</sub> reaches V<sub>ref H</sub>, the IC returns to its MONOSTABLE state.

With large values of C<sub>x</sub> and R<sub>x</sub>, and ignoring the discharge time of the capacitor and internal delays of the IC, the width of the output pulse,  $t_w$  (OUT), is as follows:

$$t_w (\text{OUT}) = 1.0 \cdot C_x \cdot R_x$$

(3) Retrigger operation

When a new trigger is applied to input  $\bar{A}$  or B while in the MONOSTABLE state, it is effective only if the IC is charging C<sub>x</sub>. The voltage level of the Rx/C<sub>x</sub> node then falls to V<sub>ref L</sub> level again. Therefore the Q output stays high if the next trigger comes in before the time period set by C<sub>x</sub> and R<sub>x</sub>.

If the 2nd trigger is very close to previous trigger, such as an occurrence during the discharge cycle, it will have no effect.

The minimum time for a trigger to be effective 2nd trigger,  $t_{rr}$  (min), depends on V<sub>CC</sub> and C<sub>x</sub>.

(4) Reset operation

In normal operation,  $\overline{\text{CLR}}$  input is held high. If  $\overline{\text{CLR}}$  is low, a trigger has no effect because the Q output is held low and the trigger control F/F is reset. Also, Q<sub>P</sub> turns on and C<sub>x</sub> is charged rapidly to V<sub>CC</sub>.

This means if  $\overline{\text{CLR}}$  input is set low, the IC goes into a wait state.

## Absolute Maximum Ratings (Note 1)

Characteristics	Symbol	Rating	Unit
Supply voltage range	$V_{CC}$	-0.5~7	V
DC input voltage	$V_{IN}$	-0.5~ $V_{CC} + 0.5$	V
DC output voltage	$V_{OUT}$	-0.5~ $V_{CC} + 0.5$	V
Input diode current	$I_{IK}$	±20	mA
Output diode current	$I_{OK}$	±20	mA
DC output current	$I_{OUT}$	±25	mA
DC $V_{CC}$ /ground current	$I_{CC}$	±50	mA
Power dissipation	$P_D$	500 (DIP) (Note 2)/180 (SOP)	mW
Storage temperature	$T_{stg}$	-65~150	°C

Note 1: Exceeding any of the absolute maximum ratings, even briefly, lead to deterioration in IC performance or even destruction.

Using continuously under heavy loads (e.g. the application of high temperature/current/voltage and the significant change in temperature, etc.) may cause this product to decrease in the reliability significantly even if the operating conditions (i.e. operating temperature/current/voltage, etc.) are within the absolute maximum ratings and the operating ranges.

Please design the appropriate reliability upon reviewing the Toshiba Semiconductor Reliability Handbook ("Handling Precautions"/"Derating Concept and Methods") and individual reliability data (i.e. reliability test report and estimated failure rate, etc).

Note 2: 500 mW in the range of  $T_a = -40\sim 65^\circ\text{C}$ . From  $T_a = 65$  to  $85^\circ\text{C}$  a derating factor of  $-10\text{ mW}/^\circ\text{C}$  shall be applied until 300 mW.

## Operating Ranges (Note 1)

Characteristics	Symbol	Rating	Unit
Supply voltage	$V_{CC}$	2~6	V
Input voltage	$V_{IN}$	0~ $V_{CC}$	V
Output voltage	$V_{OUT}$	0~ $V_{CC}$	V
Operating temperature	$T_{opr}$	-40~85	°C
Input rise and fall time ( $\overline{\text{CLR}}$ only)	$t_r, t_f$	0~1000 ( $V_{CC} = 2.0\text{ V}$ ) 0~500 ( $V_{CC} = 4.5\text{ V}$ ) 0~400 ( $V_{CC} = 6.0\text{ V}$ )	ns
External capacitor	$C_x$	No limitation (Note 2)	F
External resistor	$R_x$	≥5 k ( $V_{CC} = 2.0\text{ V}$ ) (Note 2) ≥1 k ( $V_{CC} \geq 3.0\text{ V}$ ) (Note 2)	Ω

Note 1: The operating ranges must be maintained to ensure the normal operation of the device. Unused inputs must be tied to either VCC or GND.

Note 2: The maximum allowable values of  $C_x$  and  $R_x$  are a function of leakage of capacitor  $C_x$ , the leakage of TC74HC423A, and leakage due to board layout and surface resistance.

Susceptibility to externally induced noise signals may occur for  $R_x > 1\text{ M}\Omega$ .
